

**Studies of
Transcription-Activation-Like-Effectors
Interacting with the Epigenetic Mark
N⁶-Methyl Adenine**

Dissertation

submitted for the degree of
Doctor of Natural Sciences
(Dr. rer. nat.)

presented by
Sarah Flade, M.Sc.

Technische Universität Dortmund
Faculty of Chemistry and Chemical Biology

Dortmund, 2017

This work was prepared in the time frame of October 2013 until April 2017 in the group of Prof. Dr. Daniel Summerer at the University of Konstanz and the TU Dortmund. It was funded by the Konstanz Research School Chemical Biology and the TU Dortmund.

Reproduced with the permission of Sarah Flade, Julia Jasper, Mario Gieß, Matyas Juhasz, Andeas Dankers, Grzegorz Kubik, Oliver Koch, Elmar Weinhold and Daniel Summerer, *ACS Chemical Biology*, **2017**. Copyright 2017 American Chemical Society.

DOI: 10.1021/acschembio.7b0032

Eidesstattliche Erklärung

Hiermit versichere Ich an Eides statt, dass ich die vorliegende Arbeit selbstständig verfasst habe. Alle in dieser Arbeit in Anspruch genommenen Quellen und Hilfsmittel wurden kenntlich vermerkt.

Dortmund, den 13. Juli 2017

Gutachter 1: Prof. Daniel Summerer, TU Dortmund.

Gutachter 2: Prof. Daniel Rauh, TU Dortmund.

Disputation: Dortmund, den 09. November 2017.

Fakultät für Chemie und Chemische Biologie.

Acknowledgement

Foremost, I want to express my gratitude to my supervisor Prof. Dr. Daniel Summerer for giving me the opportunity to join his research group and working on interesting and challenging projects. His excellent supervision and trust highly motivated me. He had always time for questions, valuable discussions and sharing his knowledge.

I want to thank Moritz Schmidt and Grzegorz Kubik for their kind introduction and guidance especially in the beginning when I joined the lab. I am also grateful to Preeti Rathi, Sara Maurer and Mario Gieß for their constant help and support and for joining me in the adventure of moving to Dortmund. My appreciation goes to Katharina Kuhr and Anna Witte, for their warm welcome and their support while setting up the lab in Dortmund. Simone Eppmann for her great assistance regarding many lab management questions. Álvaro Muñoz-Lopez for his friendship and great advice. Moreover, I would like to thank all bachelor and master students of the Summerer group for a nice working atmosphere and for a lot of fun inside and outside the lab.

Prof. Dr. Elmar Weinhold of the RWTH Aachen and Dr. Oliver Koch of the TU Dortmund and their teams for the fruitful collaboration on the 6mA-project.

I want to thank Prof. Dr. Malte Drescher of the University of Konstanz for the interesting collaboration on the EPR-project. The whole Drescher group for the EPR measurements and the constant exchange of knowledge and support.

I want to thank the Konstanz Research School Chemical Biology for giving me the opportunity to join their graduate program and for funding my project with a scholarship by the Research School. Also, I want to thank our neighboring working groups of the University of Konstanz and TU Dortmund for their help and freely sharing their lab equipment.

Last, I want to thank my family: My parents and my siblings for their love and support throughout my life and especially during my studies as a student. I am deeply grateful to Martin Kreutzer for his constant encouragement and motivation.

1. Introduction

1.1. Epigenetics

The human body is build up of over 200 diverse kinds of cell types, yet all share the genomic DNA sequence as an almost identical genetic blueprint.¹ This genetic information is heritable and passed on to the next generation after cell division. Even though all cells arise from the same stem cell, one genotype can result in different phenotypes. This further implies that genes determining the phenotype are permanently turned on while others are switched off. This pattern of active and inactive genes is stably kept and transferred to the new cell. When this phenomenon was discovered, the question was raised whether additional information is passed on to the daughter cell beyond the canonical DNA-sequence.

Conrad Waddington proposed in the early 1940s the term of “epigenetics”.² He coined this term as a variety of developmental processes above the level of the genome.³ Mechanisms by which the genotype of a cell emerges into several special phenotypes. Waddington knew these developmental processes were separate from the genome and he was able to bridge the gap between genotype and phenotype.⁴ If an organism is fully developed its overall genome remains stable, apart from random mutations. The functional determination, which part of the genome is transcribed and therefore which genes are expressed are based on several mechanisms. For instance, biochemical modifications at single DNA bases or histone modifications determine the accessibility of the DNA.

More than 60 years ago, it was discovered that cytosine (C) deoxynucleotides could carry methyl groups (5-methyl cytosine, 5mC) in eukaryotic genomic DNA. Since then, 5mC has been intensively studied for its role as carrier of epigenetic information. In 1975 two key publications on 5mC as well as X-chromosome inactivation due to methylation events, demonstrated that the modification of C could serve as an epigenetic mark.^{5,6} In their work Holliday, Pugh and Riggs suggested that the DNA sequence could be methylated *de novo* and that this mark could be passed on during cell division while the additional information is stored in the form of methyl groups on the DNA itself (see figure 1). They speculated that DNA binding proteins could sense and interpret the presence of methyl groups in the DNA.

Moreover, the methylation of the DNA could directly silence a gene which would bring the phenotype of a cell into being.⁷

Figure 1: Differentiation between genetics and epigenetics. A mutation is a change in the setup of the DNA and might result from imperfect DNA replication. Epigenetics on the other hand are reversible and based on alterations of gene expression or the accessibility of the gene.

1.1 Methylation of Cytosine

Today methylation of the 5th position of Cytosine is one of the best studied epigenetic modifications. 5mC is the most common modification in vertebrates. In mammalian cells this epigenetic mark predominantly appears in so called CpG dinucleotides.⁷ Regions with high CpG density at transcription starting sites (TSS) are shown to have an influence on gene control, e.g. methylation on TSS can block initiation of the DNA polymerase while the methylation on the gene body itself does not impair transcription.⁷ Other studies of targeted *de novo* methylation and demethylation revealed that genes can be switched from their expressed to their silenced state and vice versa.⁸ Another function of 5mC is to maintain the stability of the genome. Methylation of cytosine in repeat regions like centromeres are considered important for chromosomal stability due to suppression of transposons.⁹ Due to this manifold involvement in cellular processes, 5mC is an important factor to keep cellular processes functional. In normal cells, CpG islands are usually not methylated. In contrast, tumor cells exhibit global hypo-methylation of DNA. This loss of epigenetic modifications leads to methylation deficiency in repetitive DNA sequences, causing silent CpGs to become active. Moreover, coding regions as well as introns exhibit reduced methylation which finally results in chromosomal and therefore genomic instability. This further causes the reactivation of transposable elements and favors meiotic recombination.^{10,11} Along with the overall

hypo-methylation of tumor DNA, hyper-methylated tumor suppressor genes were identified.¹⁰ In contrast to normal cells, tumor suppressor genes become hyper-methylated which results in the silencing of gene expression. In this major event of cancer development many genes can be affected which play a significant role in cell cycle control, apoptosis as well as DNA repair. A known example for hyper-methylation of a tumor suppressor gene is the breast cancer susceptibility gene 1 (BRCA1) and its consequential inactivation in the development of breast cancer.¹¹ Taken together, 5mC plays a major role in regulation of gene expression and maintaining the genome stability.¹²

DNA methylation is part of a complex epigenetic network. Next to the modification of DNA, other epigenetic events are involved. For example, histone proteins do not only function in DNA packaging but their molecular structure can influence gene expression. Here, the epigenetic information is stored on the histone in form acetylation of lysine (K), methylation of K and arginine (R), as well as phosphorylation of serine (S). These modifications are post-translational introduced to the histone tails and can be in a single, double or even triple fashion, e.g. histone 3 can be single methylated at lysine residue 3 (H3K3me) which leads to activation of transcription.¹⁰ These modifications on the histone proteins influence gene transcription and DNA repair. However, this “histone code” is very complex and it is difficult to predict the outcome of a modification event, since the functional consequences do not rely on a single modification but on the interplay of several modifications. While acetylation is in general associated with activation, the outcome of methylation events depends on the targeted amino acid and the residue position within the histone tail. E.g. methylation at H3K9 and H3K20 in combination with H4K20 leads to the repression of gene transcription.^{13–16} In cancer cells, the histones exhibit a different pattern of methylation and acetylation compared to normal cells. Hence, the common interplay of histone modifications might be disrupted in cancer cells.

Epigenetic signals are reversible. The mechanism to introduce and remove, as well as maintain epigenetic marks involves participation of DNA-methyltransferases (DMT) and Demethylases. In DNA, DMTs are essential for setting up methylation patterns and catalyze the methylation of C to 5mC using S-adenosyl methionine (SAM) as methyl donor.¹⁷ For a long time it was believed that passive dilution of 5mC based on replication of the cell and absence

of methylation maintenance is the only pathway for demethylation of 5mC.¹⁸ However, with the identification of oxidized 5mC species (5-hydroxymethyl cytosine, hmC; 5-formyl cytosine, fC and 5-carboxy cytosine, caC) an active demethylation mechanism in mammals was proposed. In this active demethylation pathway 5mC is oxidized to hmC by the ten-eleven translocation dioxygenase 1 (TET1).^{19–21} Further oxidation of hmC by TET leads to fC and caC, which are used as a substrate for the thymine-DNA-glycosylase (TDG).^{19,20,22,23} In this step, TDG creates abasic sites which can be restored to C via base excision repair (see figure 2).^{8,24,25} While hmC is the most stable and abundant epigenetic modification of the cytosine derivatives known so far, the overall genomic content is variable depending on the cell type. The abundance of fC and caC shows a far lower frequency than 5mC and hmC. Despite their roles in the active demethylation pathway, the involvement of the oxidized variants in other biochemical processes is yet unclear ^{24,26–31}.

Figure 2: Methylation of cytosine by DMT and active demethylation of 5mC via the TET enzyme to higher oxidized modifications. fC and caC are catalyzed to their abasic from by TDG and are further restored to cytosine by base excision repair (BER) ³²

1.2 Adenine Methylation in Prokaryotic Genomes

Based on its widespread distribution the most common and best studied DNA modification in eukaryotes is 5mC. It exerts a dominant function by establishing the epigenetic setting and by playing a putative role in DNA-based physiological disorders like cancer. However, 5mC is mostly absent in prokaryotic genomes. By contrast, N⁶-methyl adenine (6mA) is the most dominant epigenetic mark in bacteria. 6mA entails many functions in the prokaryotic cell and methylation of A in *E. coli* occurs via the DNA adenine methyltransferase (Dam). Embedded in the sequence context of GATC, Dam transfers a methyl group to the adenine amino group using S-adenosyl methionine (SAM) as a methyl donor. The leftover S-adenosyl-homocysteine (SAH) is regenerated to SAM in an ATP-dependent reaction (see figure 3).³³ The Dam enzyme is the first methyltransferase (MTase) identified in γ -proteobacteria. It is classified as a SAM-dependent α -MTase. Based on a 10 amino acids domain, Dam shares significant homology with DpnIIA and MboIA methyltransferases. The Dam MTase is widespread in enteric bacteria and can be found e.g. in *Salmonella spp.*, *Yersinia spp.* and *Vibrio cholerae*.³³ Commonly, methylation occurs after DNA replication. The replication fork passes the methylation site trailed by Dam which processes hemi- and unmethylated GATC with similar efficiency.³⁴ Since the Dam enzyme can be a *de novo* or a *maintenance* MTase, 6mA acts as a transient or stable epigenetic mark depending on the event.^{34,35}

Figure 3: The DNA nucleobase adenosine (A) is modified to its epigenetic version of N⁶-methyl-adenosine (6mA) by the transfer of a methyl group. This transfer is performed by methyltransferases and can be reversible. Image from ³⁶

1.2.1 Adenine Methylation during DNA Replication

6mA is involved in sister-strand synthesis in *E. coli*. Only in the presence of methylated adenine at the origin of replication (*oriC*) the initiator protein DnaA binds and separates the two DNA strands.³⁷ During DNA replication, GATC sites of *oriC* are not immediately fully methylated but remain hemi-methylated for a major part of the cell cycle. Consequently, the newly synthesized DNA does not carry 6mA as a signal and *de novo* methylation is hindered by the protein named SeqA, which negatively regulates initiation of DNA replication. This hemi-methylated state of the *oriC* prevents the start of a new replication cycle.^{35,38} Additionally, the discrimination of non-methylated daughter strands enables *E. coli* to employ the methylated parental strand as a template for mismatched DNA bases guided by recognition of the MutHLS protein complex.³⁹

1.2.2 Adenine Methylation for Genome Defense

6mA functions as signal for genome defense embedded in the restriction-modification-system (RM). The RM-system is believed to be evolved protecting bacteria against bacteriophages and can be found in many prokaryotic and archaeal life forms. It distinguishes between host DNA and foreign invader DNA.⁴⁰ The RM-system encodes pairs of intracellular enzyme activities: An endonuclease and its opposing partner DNA methyltransferase.⁴¹ The endonuclease cleaves invading viral DNA at short recognition sites which are not modified by methylation. Meanwhile, the host DNA is protected by 6mA. The unmodified invading DNA is rarely methylated fast enough to be protected from restriction and thus the RM-system provides a simple form of genome protection along with self and non-self-discrimination (see figure 4).³³

Figure 4: Functions of adenine methylation in prokaryotic genomes. 6mA plays a role in the protection of the genome against viruses. Also, it is involved in DNA replication, sister strand synthesis and the repair of mismatched DNA. The establishment of pathogenic virulence and adhesins expression via phase variation are also 6mA mediated. Image is adapted from ³³.

1.2.3 Adenine Methylation in the Regulation of Virulence Factors

Another task of 6mA is the regulation of virulence factors. Uropathogenic *E. coli* harbor a pyelonephritis-associated pili (pap)-operon, which encodes fimbrial adhesins that allow the pathogen to adhere to the urinary tract epithelium. Normally, the pap operon is switched off, based on distinctive methylation pattern in the pap regulatory region.⁴² This regulatory region contains two GATC sites (proximal and distal). In the off state, the Leucine responsive protein (Lrp) is bound at three downstream sites blocking RNA polymerase transcription. This binding of Lrp additionally reduces the affinity of Lrp-upstream binding, creating a feedback loop to keep the operon state switched off.⁴³ While the Lrp protein binds to the downstream site, methylation of the proximal GATC is prevented. The distal GATC is free and becomes methylated. This off state is kept, until the PapI protein is present.⁴² Above a critical threshold, the switching factor PapI stimulates the Lrp translocation from downstream to upstream binding site. Distal GATC methylation is now prevented, while proximal GATC is methylated promoting the on state of the pap operon. A positive feedback loop sustains the on state and allows expression of fimbrial adhesins. Thus, the pathogen is able to invade the urinary bladder and cause urinary tract infection (see figure 5).^{33,42,44,45}

Figure 5: Schematic display of the Pap operon. This regulatory domain comprises two GATC motifs which can exhibit a differential methylation status. This pattern allows the expression of fimbrial adhesins to promote the invasion and adhesion to the urinary mucosa and finally results in tract infection.

1.3 Adenine Methylation in Eukaryotic Genomes

5mC and 6mA were discovered almost simultaneously a few decades ago. However, at that time research of 6mA was mainly focused on prokaryotic genomes. Due to the low abundance of 6mA in higher organisms and constraints in technological detection its potential epigenetic function has remained elusive until recently. With the use of highly sensitive modern mass spectrometry it became possible to detect trace amounts present in the cells, usually in the range of parts per million. This low occurrence, compared to 5mC, raised further doubts about the functional significance of 6mA in multicellular organisms and vertebrate tissue.⁴⁶⁻⁴⁸ Nevertheless, a few early reports existed which accounted the presence of 6mA in eukaryotic DNA. Unicellular eukaryotes like ciliates and green algae were reported to contain both 6mA and 5mC in their genomes.⁴⁹ However, the biological relevance of 6mA regarding involvement in epigenetic processes in higher organisms had remained vague.

In May 2015 studies have shown the abundance of 6mA in three phylogenetically distinct eukaryotes *Chlamydomonas reinhardtii*⁵⁰, *Drosophila melanogaster*⁵¹ and *Caenorhabditis elegans*⁵². First indications of potential epigenetic functions of 6mA in eukaryotic genomes were described along with new detection methods like UHPLC-MRM-MS/MS (ultra-high-performance liquid chromatography-triple quadrupole mass spectrometry), 6mA targeted MeDIP-sequencing and other restriction assisted sequencing of DNA samples containing 6mA.⁵³ Parallel studies on claw frog (*Xenopus laevis*)⁵⁴ and zebrafish (*Danio rerio*)⁵⁵ attracted further attention to eukaryotic 6mA and spurred speculations how widespread this modification could be in vertebrates and mammalian genomes.^{36,56,57} Soon the occurrence of methylated adenine in mouse embryonic stem cells (mESC) was published⁵⁸ and has been questioned⁵⁹. Interestingly, the abundance of 6mA seemed to vary: Most tested organisms and tissues exhibited minute levels of 6mA (e.g. 0.00009 % 6mA/A in *Xenopus*), except for the green algae, which displayed the presence of 6mA in 84 % of all genes. In case of the fruit fly the levels of 6mA are dependent on the developmental stage of the organism. In the embryogenesis of *Drosophila*, the abundance of 6mA shows a 70-fold increase in initial stages compared to the adult stage (from 0.001 % to 0.07 % A/6mA). Comparable results were obtained in zebrafish and mice. The content of methylated adenine is doubled in the zebrafish zygote and increased further to a maximum of 0.1 % A/6mA in the 32/64 cell stadium. With the progressing development of the zebrafish, the abundance of 6mA dropped indicating a

role in the functional regulation of embryogenesis. While methylated adenine is evenly distributed in *C. elegans*, it is highly enriched in transcription starting sites in *C. reinhardtii* and in transposable elements of *D. melanogaster* implying not only a single role for eukaryotic 6mA but also a species-specific function.

Moreover, the studies revealed the existence of several 6mA-introducing and removing enzymes. In *D. melanogaster*, *C. elegans* and mESC 6mA-demethylases (and methyltransferase DAMT1 in the case of *C. elegans*) could be identified. In the fruit fly, the demethylase DMAD (diogxgenase *Drosophila* DNA 6mA demethylase) showed similar structural domains as the mammalian TET-enzyme. It was shown that this demethylase is specific for 6mA and does not demethylate 5mC, hmC or 6mA in RNA. Alterations in the expression of the demethylase lead to increased lethality of the *Drosophila* embryo. Comparable to these findings, deficiency of the identified mouse Alkbh1 demethylase caused reduction in litter size and resulted finally in embryonic lethality indicating a regulation mechanism for 6mA.

Taken together these recent findings imply functional epigenetic roles of 6mA. In RNA, the profound effects of adenine methylation are extensively studied. In mammalian non-coding RNA and mRNA, 6mA can be catalyzed by demethylases generating intermediates like N⁶-hydroxymethyl adenine (6hmA) and N⁶-fomyl adenine (6fA). Since these recently discovered 6mA variants are stable modifications in RNA, they might possess regulatory functions.⁶⁰ Furthermore, RNA carrying an adenine methyl group can be destabilized regarding Watson-Crick base-pairing to induce a switching mechanism that alters the RNA structure. Thus, binding of proteins to RNA can be influenced by the presence as well as the positioning of 6mA at the protein binding site. The same feature could be assigned to adenine N⁶-methyl groups present in DNA. It could affect gene transcription and inhibit or facilitate the binding of transcription factors or other DNA binding proteins.

Since *C. elegans* and *D. melanogaster* have little or no 5mC in their genome, it is possible that the altering presence of this modification compared to other higher organisms, is the result of evolutionary events.^{56,57} Here, 6mA could play a predominant role in epigenetic processes and the identification of 6mA demethylases and methyltransferases implies that adenine methylation could be present in many more organisms. With the ongoing development and

continuous improvement of sensitive detection techniques, the function and precise distribution of eukaryotic 6mA could be explored throughout all domains of life (see figure 6).

Figure 6: Overview of 6mA which was predominantly present in bacteria and archaea until recent findings. Three studies in phylogenetically distinct organisms reported the presence of 6mA in eukaryotic genomes. Further publications illuminated the abundance of 6mA in higher organisms like amphibia and mammals. Image was adapted from ³⁶.

1.4 Transcription-Activator-Like Effector Proteins

Transcription-activator-like effectors (TALEs) are DNA binding proteins that are injected into plant cells by numerous phytopathogenic bacteria. After transfer to the host cell via the type III secretion system the TALE protein enters the nucleus and binds to effector specific promoters.⁶¹ Subsequently this will impair the host defense mechanisms or trigger a response beneficial for the bacterium. TALE effectors are key virulence factors for plant pathogens and can reprogram plant cells into mimicking eukaryotic transcription factors.⁶² TALEs have been found predominantly in species of *Xanthomonas*, but related homologs exist in *Ralstonia solanacearum* and *Burkholderia rhizoxinica* as well.^{63,64}

Figure 7: Crystal structure of the TALE protein PthXo1 binding to its target DNA from top view (left) and side view (right). The TALE (light blue) wraps itself along the major groove of the target DNA (blue) via concatenated repeats facilitating recognition and binding of the protein. Adapted from ⁶⁵ and PDB entry 3UGM.

The central DNA binding domain of TALEs consist of a unique structure which shows no similarity to known DNA binding proteins. In 2009, Boch and Bonas presented the setup of this central domain, along with the study of Moscou and Bogdanove which confirmed their findings by computational analysis.^{66,67} Soon after the first reports on TALEs its crystal structure (see figure 7) was elucidated.⁶⁵ The high modularity enabled the development of

toolkits for customized TALE assembly. These are often based on Golden Gate cloning^{68,69,65,71}, but also methods combining solid phase synthesis and standard cloning like fast ligation based automatable solid-phase high throughput (FLASH) exist. A detailed protocol on how the TALEs proteins are cloned in a Golden Gate (GG) approach is presented in section 6.2.

1.4.1 TALE Scaffold and Binding Mode

TALE proteins are composed of three major parts: The N-terminal region (NTR), the central DNA binding domain and the C-terminal region (CTR). In Nature, the N-terminus of the protein contains the type III secretion signal which provides access to the host plant. The C-terminal region bears the nucleus localization sequence (NLS) as well as an activator domain. While the N-terminus binds the 5'-end of the target DNA, the C-terminal region faces the 3'-end. In between the N- and C-terminus the central repeat domain (CRD) is located. The CRD consists of tandem, concatenated repeats which each comprise 33 to 35 amino acids. These repeats are nearly identical and highly conserved except for the amino acid position 12 and 13. These positions are called repeat variable di-residues (RVD) and facilitate the TAL effector binding to the DNA sequence. TALEs recognize their target DNA via a simple one-to-one code (see figure 8): In nature, several RVDs are observed, however the most naturally occurring RVDs are HD, NG, NN and NI which respectively specify the DNA nucleobases C, T, G/A and A. Other less frequent RVDs like NS and N* exhibit loose specificity (the asterisk incorporates a missing amino acid at position 13 forming a 33 amino acid repeat).^{72,73} RVDs NH and NK are less common and show increased specificity for guanine (G). The central repeat domain is terminated with a truncated repeat containing the first 20 amino acids and is commonly referred to as half or last repeat (LR).⁶⁶

Each TALE repeat consists of two α -helices with the RVD residing in an interhelical loop domain. The residue at position 12 in each RVD is facing away from the DNA interacting with the proteins' backbone carbonyl at position 8 thus stabilizing the interhelical loop. The residue at position 13 faces the DNA and looms deep into the major groove facilitating sequence-specific contact with a single DNA nucleobase (see figure 8). It has been observed that most contacts between the RVD and DNA bases are resulting from direct hydrogen bonds (e.g. HD in contact with cytosine between the aspartate (D) carboxyl-group and 4-amino group of C),

highly steric packing (e.g. alpha carbon of glycine (G) of NG to extra cyclic methyl carbon of thymine base) or reduced specificity via steric exclusion of alternative DNA nucleobases (NI RVD).⁷⁴ Moreover, studies revealed that HD and NN repeats procure a significant contribution to overall TALE binding affinity, while NI and N* repeats appear to result in reduced activity and lower specificity.⁷³ Depending on the target sequence context selectivity effects have been reported.^{75,76}

Figure 8: Framework of TAL effector proteins. Each TALEs consists of multiple concatenated, conserved repeats which comprise 34 amino acids (left). Position 12 and 13 of each repeat are variable residues (RVD) and form a loop which is embedded into two α -helices (below). The RVDs of the TALE protein facilitate the contact and binding to the target DNA and follow a simple cipher in which the RVDs NI, NN, NG and HD specifically recognize A, G/A, T and C nucleobases (right). Adapted from ⁷⁷.

Besides the CRD, the N-terminus of TALE proteins also plays a key role when it comes to DNA binding. Crystallographic resolution of the N-terminus illuminated that this region is crucial for full activity of TALE proteins.⁷⁸ Although the underlying mechanism is not yet well understood it was shown that the NTR comprises 4 continuous “cryptic” repeats analogous to the canonical repeats of the CRD. These additional N-terminal repeats follow the TALE taxonomy and are named repeat 0, -1, -2 and -3. The cryptic repeats provide the main part of binding energy. They exhibit positively charged patches evoked by arginine and lysine residues.^{78,79} These conserved residues contribute to the overall basic charge of the TAL

protein implying promoted nucleic acid binding by the NTR, however, this binding occurs to be non-specific and sequence independent of the target DNA .^{78,80,81}

Despite deciphering the TALE code and insights of the binding affinity of TALE proteins to DNA, little is known how the proteins search and recognize their target. Studies of other DNA binding proteins observed either a mechanical salt-dependent “hopping mechanism” in which the protein is involved in cycles of binding and unbinding to the DNA or a “sliding mechanism” whereas the protein slides along the DNA helix. TALE proteins have been described to be a hybrid of both.⁸² A model suggested that TALE proteins take a conformation wrapping itself loosely along the DNA helix during nonspecific search. Upon encountering a target site, TALEs compress and “verify” the local sequence thus resulting presumably in stable binding.

1.4.2 DNA Binding Proteins and TALE Applications

In the past decade, several approaches have emerged which offer targeting and manipulation of any gene of interest from a wide range of different cell types and organisms. The discovery of programmable proteins like TALEs, Clustered Regularly Interspaced Short Palindromic Repeats (CRISPR-CAS) and Zinc Fingers (ZF) equipped scientists with an unmatched ability to alter cells and organisms in their genomic setup. In the case of TALEs and ZFs the versatility of is based on the modularity of the DNA binding domain enabling recognition of any DNA sequence. Zinc Fingers consist of 30 amino acids and contain two conserved pairs of cysteines and histidines which are stabilized by one zinc ion. Each finger is built-upon an antiparallel β -sheet recognizing 3 to 4 DNA nucleotides and inserting an α -helix structure into the major groove of the DNA. ZFs were the first programmable DNA binding proteins harnessing genome editing approaches. However, design and selection of each ZF turned out to be laborious and time consuming since neighboring ZFs influenced specificity and enhanced off target effects. The fortuitous discovery of TALEs offered an easier assembly approach. The TALE modules appeared to be mostly independent of neighboring influences and were publicly available, which allowed inexpensive and quick generation of custom TALEs. Only 3 years after the TALE recognition mode was decoded, the CRISPR-CAS platform was developed. While TALEs and Zinc Fingers exhibit highly modular DNA binding domains, the CRISPR-CAS system relies on RNA-DNA recognition. The advantage of the CRISPR-CAS system is based on the easy RNA design and a single constant Cas9 nuclease. For DNA cleavage, the Cas9 is guided by an RNA (gRNA) which will hybridize to its target DNA sequence to facilitate binding of the CRISPR-CAS system. CRISPR-CAS has been shown to be effective in most established model organisms and cell cultures. However, it showed off target effects just like TALEs and Zinc Fingers. In all three protein models, most off-target and specificity problems have been overcome by simple adjustments e.g. truncation of the gRNA. The most exciting aspects of these DNA targeting proteins is how efficiently they have been used and how broad their effective application can be reported in many model organisms from crop plants and livestock to humans. For example, TALEs can be exploited for gene editing. Hereby the protein is fused to a nuclease domain (e.g. TALE with FokI domain) and introduces double strand breaks *in vivo* which are repaired by non-homologous end joining (NHEJ) or homologous recombination (HR). Thus, deletions, insertions or mutations can be established in the genome. Moreover, DNA binding proteins can be harnessed for tracking or imaging studies when connected to a

fluorescent domain like GFP (green fluorescent protein). Likewise, the fusion of the DNA binding protein to a transcriptional regulator facilitates expression or inhibition of the target gene. Besides alterations to the genome, the epigenome can also be manipulated. A study showed that site specific removal of cytosine methylation is possible by cloning TET catalytic domains to TALE proteins.⁸³ Similarly, TALEs linked to histone demethylase protein LSD1 altered histone methylation and the introduction of methylation by fusing TALE proteins with methyltransferases has been reported to be successful.⁶⁸⁻⁷¹

1.4.3 TALEs and Epigenetics

TALE proteins can also be used for targeted transcription regulation and altering the epigenetic setup. A critical property of TALEs is their central DNA binding domain. For any genome targeting approach high sequence selectivity is required. Consequently, to avoid any off target binding effects of TALEs, maximal RVD selectivity is needed and studies on mutational analysis have offered improved RVDs.^{87,88} Interestingly, another critical characteristic of TALEs is their sensitivity towards DNA nucleobases which carry epigenetic modifications. For instance, the RVD HD is shown to be sensitive to 5mC. If 5mC is present in the target sequence, TALE binding is abolished.⁸⁹⁻⁹¹ 5mC has been identified to be present in CpG islands embedded in many promotor regions. This critical regulatory element is generally chosen for knock out studies of genes with therapeutic and biotechnological interest. This negative impact on TALE binding has led to the development of customized RVDs which exhibit similar binding affinity to C and 5mC.⁸⁹ It was suggested that the TALE repeat N* can efficiently accommodate methylated cytosine and thus overcome the methylation sensitivity of TALEs. However, this discriminatory binding affinity can also be exploited to develop TALE repeats binding to the full range of epigenetic modified nucleobases like 5hmC, 5fC and 5caC.^{12,92-94} Moreover, binding affinities of TALEs to other modified DNA like 6mA or N⁴-methyl cytosine (N4mC) bases are yet unknown. In the light of recent studies of 6mA being present in eukaryotic genomes in organisms from all domains of life, it is important to understand and investigate the specific binding capability of TALEs to this epigenetic nucleobase.

2. Aim of Work

The specific detection of epigenetic marks might open the door for the diagnosis and subsequent treatment of numerous diseases which are based on a disorder of the DNA methylation pattern as known for the case of 5mC. In the past decade, lots of effort went into the development of protein-DNA recognition systems. The present work is located at the interface of DNA-protein interaction studies and the influence of epigenetic signals with the specific task to illuminate the binding behavior of TALEs to DNA harboring 6mA modifications. The first step is the interrogation of the RVD NI interacting with DNA representing naturally occurring methylation sites in uropathogenic *E. coli* (Pap operon). For further insights, the canonical NI will be mutated to RVDs facilitating a less polar surface and the resulting interaction with 6mA will be examined. Moreover, polar RVDs will be created which could enable H-bonding to the N⁶-amino group or N⁷-O-atom of adenine and thus exhibit differential TALE binding. DNA. A second approach is the expansion of the N⁶-methyl group with bulkier substituents in the form of SAM analogs, which can be transferred to the GATC motif by the Dam methyltransferase. Here, we interrogate the ability of TALEs to accept large groups facing the major groove of the DNA paving the way for smart TALE design and labeling strategies with bulky fluorophore labels.

3. Results and Discussion

3.1 Selection of TALE Target-DNA

For the interrogation of TALE binding affinity to epigenetically modified DNA a sequence context was chosen which is regulated via the reversible methylation of adenine. Two naturally occurring 17-nucleotide long sequences, namely Pap2 and Pap5 were chosen. Both hold a regulatory GATC site within the *E. coli* pap operon (see figure 9). Methylation of the N⁶-position of adenine within the proximal (Pap2) and distal (Pap5) GATC site occurs via the Dam methyltransferase. The methylation determines binding of the leucine-responsive regulatory protein and leads to the expression of pyelonephritis-associated pili (Pap). Ultimately this results in the adhesion of uropathogenic *E. coli* (UPEC) to the mucosa cells as a basic mechanism for many urinary tract infections.^{42,44,45,95}

Figure 9: Overview of selected target DNA sequence for TALE targeting. The GATC sites are underlined with A or 6mA of interest in red. The sequences are 17 nucleotides (nt) long and the nucleobase of interest is located at position 7 of the oligos. Additional truncated oligos were designed for a later investigation sequence length dependency of TALE proteins. Adapted from ⁷⁷.

3.2 TALE Assembly and Expression

The TALE proteins used in this work were generated based on the *Xanthomonas axonopodis* scaffold. A protocol for the respective golden gate assembly was established by the group of Daniel Voytas.^{96,97} Hereby, the constructed TALE proteins contain a truncated N-terminus (+136 amino acids from the first canonical repeat) which harbors a thioredoxin (TRX) or green fluorescent protein (GFP)-tag. In contrast to natural TALEs, the proteins assembled in the lab lack the translocation signal, the nuclear localization signal (NLS) and the activation domain

in the C-terminus. The TALE repeat arrays were assembled according to the sequences of Pap2 and Pap5. After the first and second round of the Golden Gate reaction the *E. coli* BL21 cells were transformed with the generated plasmids for selection. The protein was isolated and purified via C-terminal His6 affinity tag by Ni-NTA chromatography. The purity and correct protein size was verified by SDS-PAGE analysis (see figure 10). For detailed description of TALE assembly and expression see methods 6.2.2 and 6.2.3.

Figure 10: Exemplary image of 8 % SDS resolving gel containing expressed and purified TALE proteins with thioredoxin tag. From left to right: TALE_Pap2_NI, TALE_Pap2_NL and TALE_Pap2_NV (first and second elution). Constructed TALEs contain 17 repeats (including T_0) and carry a mass of approx. 86.32 kDa. As a marker, the protein broad range maker from NEB was used (2-212 kDa, P7702S). Image is adapted from ⁷⁷.

3.3 TALE-Binding to N⁶-Methyl Adenine

3.3.1 Interrogation of the natural RVD NI binding to A and 6mA

NI is the most frequently found natural occurring RVD in TALEs for binding of the nucleobase A.^{66,67,87,98} However, it is unknown how the NI TALE repeat interacts with an N⁶-methylated adenine. The steric changes introduced by the N⁶-methyl group might weaken or abolish the target affinity. It is well known that isoleucine at position 13 in the RVD NI (I13) generates a hydrophobic surface at the Hoogsteen face of A. Crystal structures report atomic distances between 3.8 and 4.1 angstrom between A and I13 (see figure 11).^{65,99}

Figure 11: Crystal Structure of the RVD NI to the nucleobase adenine (A). Dotted lines indicated the distances from position 12 and 13 in angstrom. Adapted from⁷⁷.

Furthermore, a hydrophobic interaction between the N⁶-amino hydrogen of A and the O⁴ of a paired thymine nucleobase might move the N⁶-methyl group towards the side chain of I13. Therefore, an interaction of the TALE RVD NI with 6mA seems possible. To test this hypothesis, expressed TALEs (Pap2_NI) were employed in electromobility shift assays (EMSA) using a GFP fluorophore tag as a read out. TALEs targeting the Pap2 sequence were incubated together with unlabeled DNA oligonucleotide duplexes comprising either A or 6mA at position 7 opposite the TALEs RVD NI. The result displayed the formation of defined TALE-DNA complexes with increased electromobility in comparison to sole TALE protein. Interestingly the results do not show differences in TALE binding to DNA containing either A or 6mA (see figure 12).

TALE_Pap2_NI protein. Eventually, dNTPs and Klenow Fragment were added to the mixture and further incubated. The reaction was resolved and monitored by denaturing polyacrylamide gel electrophoresis (PAGE) with 9 M urea. The extension product of the PAGE gel was quantified and employed as a measure of TALE binding (see figure 14).

Figure 14: Primer extension assay with TALE_Pap2_NI binding to DNA oligo complexes. **B:** Image of urea PAGE gel with reactions containing 25 mU Klenow Fragment (exo-), 41.5 μ M dNTP, 8.325 primer-template complex and various concentrations of TALE_Pap2_NI (541 nM, 333 nM, 166.5 nM and 8.32 nM) resulting in the displayed TALE/DNA ratios. **B:** Quantification of urea PAGE gel as a measure of TALE binding to A and 6mA (n=3). The image was adapted from ⁷⁷.

Despite greater sensitivity the primer extension assay also showed no differences in TALE_Pap2 binding. The same result was observed over varying TALE concentrations. Similarly, targeting the Pap5 sequence context yielded the same results. In order to exclude masking of potential selectivity caused by excessive binding energy, the experiments were repeated with truncated TALE_Pap2_NI variants. To achieve this, the truncated TALE versions were targeting only 16 or 15 nt Pap2 DNA duplexes. Again, no differences could be detected in the primer extension assay (see figure 15). A possible explanation is the probable accommodation and tolerance of 6mA by the RVD NI. Both experiments suggest additionally, that the N⁶-methyl group is barely involved in hydrophobic interactions with TALE.

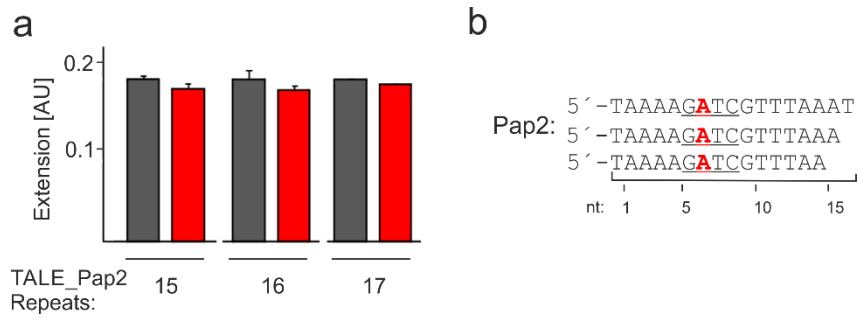

Figure 15: Primer extension assay with truncated TALE_Pap2_NI binding to DNA oligo complexes with 17, 16 and 15 nt. **A:** Quantification of the extension product as a measure of TALE binding in the primer extension assay ($n=3$). **B:** Pap2 sequence context with truncated versions used in this experiment. The nucleobase A or 6mA (red) is embedded in the GATC sequence. Adapted from ⁷⁷.

3.3.2 Interrogation of Non-Polar RVDs Binding to A and 6mA

Previous structural studies reported that adenine can be harbored by RVDs which carry a mutation in the amino acids at position 13. In the RVD NI the hydrophobic side chain directly faces the A nucleobase without favorable contact and may not exhibit a major contribution to the overall TALE affinity to DNA. Thus, NI was reported to be a weak RVD^{73,99}. However, it also indicates that isoleucine (see results 3.3.1) and another wide range of amino acids at position 13 could tolerate adenine and possibly N⁶-methyl adenine when there is no steric clash. Mutants with hydrophobic amino acids at position 13 seem to accommodate the adenine nucleobase but this remains still elusive.⁹⁹ For further modulation of the hydrophobic surface of the RVD NI, the position 13 was replaced by a shorter valine (V) and a more flexible leucine (L). The generated RVDs NV and NL can provide deeper insights into the interaction of TALE proteins with 6mA. For testing the mutated RVDs, TALEs were generated that targets again the Pap2 sequence context. The RVDs were positioned opposite A or 6mA and primer extension experiments were carried out (TALE_Pap2_NL and TALE_Pap2_NV). In both cases, the TALE proteins exhibited similar binding to the DNA target compared to the wildtype RVD NI (see figure 16).

Figure 16: Modulation of the hydrophobic surface of RVD NI. **A:** Principle of the TALE scaffold carrying the RVD NL, NV or NI at position 7, which is placed opposite A or 6mA. The mutations represent hydrophobic shorter (V) or more flexible (L) sidechains facing the nucleobase A or 6mA. **B:** Quantification of the primer extension assay as a measure of TALE binding carrying the RVDs NL and NV compared to wildtype NI (n=3). Adapted from⁷⁷.

This observation was also consistent for the Pap5 context (see figure 17). These findings imply that non-polar hydrophobic RVDs NI and NV accommodate A and 6mA without specific coordination and affinity. Furthermore, the N⁶-methyl group is tolerated and does not lead to a steric clash. This pronounced flexibility prevents hydrophobic interactions and is consistent with reported crystal structures ⁹⁹.

Figure 17: Quantification of the primer extension assay as a measure of TALE binding carrying the RVDs NL and NV compared to wildtype NI. Modulation of the hydrophobic surface of RVD NI. The mutations represent hydrophobic shorter (V) or more flexible (L) sidechains facing the nucleobase A or 6mA. Here the Pap5 sequence context was tested with TALE_Pap5 comprising either NI, NL or NV at repeat position 7. Adapted from ⁷⁷

To verify these data, models of TALE_Pap2_NI, TALE_Pap2_NV and TALE_Pap2_NL were conducted based on available crystal structures. All models were generated with DNA containing either A or 6mA at position 7 of the Pap2 operon. The model for the wildtype RVD NI displays the rotation of the terminal methyl group in the side chain of I13 to accommodate 6mA. Similarly, a conformational change can be observed for L13. Both amino acid side chains prevent unfavorable interaction with the N⁶-methyl group via slight conformational changes. For the shorter side chain of V13 compared to I13 and L13, a larger distance to the nucleobase is revealed. Here, no rotation is observed for the accommodation of 6mA. All three models suggest that the N⁶-methyl group can be harbored in the RVD variants. The larger sidechains of NI and NL adapt and slightly rotate to conformations avoiding steric clash. The amino acids do not undergo hydrophobic interactions that lead to a measurable change in selectivity (see figure 18).

Figure 18: Superimposed models of TALE_Pap2 with mutated RVD containing I13, L13 or V13 (red). The TALE is shown as cartoon and binds to DNA carrying A or 6mA opposite the relevant RVD. Model containing A is displayed in gray, 6mA in light brown. **A:** The RVD with Ile at position 13 interaction with A and 6mA. **B:** RVD NL interacting with A and 6mA. **C:** Model of RVD NV opposite of A or 6mA. Models were created in collaboration with Julia Jaspers and Oliver Koch, TU Dortmund.

3.3.3 Interrogation of Polar RVDs Binding to A and 6mA

Previous studies have described that hydrophobic RVD mutants do not clash with adenine. This finding is consistent with the results of the present work. Models of RVD variants containing non-polar amino acids like proline, methionine and cysteine can accommodate the nucleobase adenine and therefore do not give rise to any steric constraints. Similarly, it has been reported that polar amino acids which do not form an H-bond to the opposite adenine adapt a conformation to avoid a steric clash.⁹⁹ The naturally occurring RVD NN with polar asparagine (N13) is known to bind both, adenine and guanine. Crystal structures have unveiled that the side chain amide group of N13 forms an H-bond with the N⁷-atom of adenine.⁹⁹ Yet, the binding affinity of NN with its polar surface to 6mA is unknown. Therefore, primer extensions with the RVD NN embedded in TALE_Pap2 were performed. The results exhibit similar binding to A and 6mA. The N⁶-methyl group shows little influence of the overall TALE binding affinity (see figure 19). Modelling of TALE_Pap2 with RVD NN indicate, that the N13 slightly rotates accommodating the methyl group of 6mA which results in a loss of the H-bond to the N⁷-amino group.

Figure 19: Interaction of TALE_Pap2 containing the polar RVD NN with A and 6mA. **A:** Quantification of primer extension. The TALE/DNA ratio was 60:1 (n=3). **B:** Superimposed modelling of TALE_Pap2_NN interacting with A (gray) or 6mA (light brown). Red dotted line indicates H-bonding. Models were created by Julia Jaspers and Oliver Koch, TU Dortmund.

The next experiment was to examine the polar RVD NE. This RVD contains glutamic acid (E) at position 13 of the repeat. Reported *in vivo* activity assays with TALE nucleases utilizing NE

showed no binding to the nucleobase A.^{87,100} However, the models indicate that the side chain of E13 can reach further towards the major groove of the DNA and therefore direct H-bonding with the N⁶-methyl group can be observed in the crystal structure.⁹⁹ These observations suggest that the binding of the RVD NE to 6mA could experience more influence by the N⁶-methyl group. Surprisingly, the performed primer extensions did not indicate differences in binding of TALE_Pap2_NE to A or 6mA. Modelling of this interaction supports the hypothesis that the side chain of E13 reorients itself to accommodate the nucleobase. This results in a loss of the hydrogen bond to the adenine N⁶-methyl group. Furthermore, NE forms a hydrogen bond to its own backbone amide. This conformational change causes the precedent RVD to rearrange in order to avoid an unfavorable steric clash (see figure 20)

Figure 20: Interaction of TALE_Pap2 containing the polar RVD NE with A and 6mA. **A:** Quantification of primer extension. The TALE/DNA ratio was 60:1. **B:** Superimposed modelling of TALE_Pap2_NN interacting with A (gray) or 6mA (light brown). Models were created by Julia Jaspers and Oliver Koch, TU Dortmund.

Taken together, the findings of non-polar RVDs (NI, NL and NV) as well as polar RVDs (NN, NE) do not exhibit differential binding to A or 6mA with the respective TALE protein. This indicates that the TALE repeat framework is not selective towards A and 6mA. The methylation insensitivity allows robust binding of the DNA by the TALE protein and enables user-defined binding to DNA loci which potentially contain epigenetically modified adenine. This makes it a useful tool for *in vivo* applications, where actual epigenetic modifications could occur depending on the target sequence. Consequently, testing TALEs with varied RVDs placed opposite other DNA nucleobases like thymine, cytidine and guanine did not result in

differential binding. These data indicate that TALE repeats have a high intrinsic motility to undergo conformational changes while accommodating A and 6mA while remaining a robust DNA binder.

3.4 Interrogation of TALEs to Bulky N⁶-Alkynyl Substituents

The tolerance of TALEs harboring methyl groups at the N⁶-position of adenine raised the question if the protein can accommodate even larger substituents at this position. The recognition and binding mode of TALE proteins is directed towards the DNA major groove. This feature makes TALE proteins a useful capture tool for analytical approaches. For example, TALEs sensitive to methylation of cytosine can be used as selective fishing tools for DNA containing epigenetic bases like 5mC and 5hmC, thus delivering information about the presence and status of modified cytosine embedded in DNA samples based on TALE binding or abolished binding.^{12,32,92,93,101,102} All these applications would profit of fluorescently labeled DNA for detection. However, the optimal site to attach DNA labels is the 5-position of cytosine and thymine directed towards the DNA major groove. This site is recognized by methylation sensitive TALEs and could abolish binding. Thus, the N⁶-position could be an ideal site to introduce DNA labels which are tolerated during TALE binding. This blind spot could enable effective binding of TALE proteins to methylated and fluorophore-labeled DNA. Therefore, it was intriguing to investigate the introduction of larger substituents at this position.

For the introduction of a label at the adenine position, S-adenosyl methionine (SAM) analogs were used. In nature, SAM is a common cosubstrate for enzymes which are involved in the transfer of methyl groups. In this process SAM is hydrolyzed to S-adenosyl homocysteine (SAH) and adenine. In bacteria, the Dam methyltransferase utilizes SAM to transfer a CH₃-group to the N⁶-position of adenine. For the approach of interrogating larger substituents, the Dam enzyme represents a practical tool to introduce labels in the form of SAM analogs at adenine. The SAM analogs contain alkynyl-substituents which replace the electrophilic methyl group at the sulfonium center and therefore enlarge the moiety of the replaced methyl group. The SAM analogs were synthesized and then tested for acceptance by the Dam enzyme. In this assay, SAM-free Dam enzyme is needed to ensure a high yield of transferred groups and to avoid preference of the common SAM cofactor. The obtained results indicate that the synthesized SAM analogs are accepted by the Dam enzyme and that the substituents were successfully transferred to the A position within the GATC motif. The synthesis of the SAM variants, as well as the testing of the Dam tolerance was conducted in collaboration with the group of Elmar Weinhold, RWTH Aachen (see figure 21).

Figure 21: Modification of adenine at the N⁶-position embedded in the GATC motif of the pap operon (Pap2). The *E. coli* Dam enzyme transfers a methyl group from the SAM substrate to adenine (2a). In the reaction homocysteine (SAH) is produced. Other SAM analogs (1b and 1c) are accepted by the Dam transferase and can be transferred to the N⁶-position of adenine (2b and 2c). The SAM analogs as well as the expression of SAM-free Dam enzyme were provided by the group of Elmar Weinhold, RWTH Aachen.

In our approach, we interrogated if labeled DNA would interfere with TALE binding. The SAM analog 1b was of special interest. This alkyne substituent exhibits a certain flexibility and does not hold a branched structure. Another advantage is, that 1b can be used for posterior labeling. Via the Cu(I)-catalyzed [3+2] azide-alkyne cycloaddition further labels and fluorophores can be introduced. To test our hypothesis, DNA duplexes with the sequence context of the pap operon 2 were modified by the Dam enzyme with SAM and other synthesized SAM analogs (see also methods 6.2.4). After the transfer of the group of interest (1a, b or c) to the N⁶-position of adenine, the DNA was purified and subjected to mass spectrometry. The analysis by electrospray ionization time-of-flight (ESI-TOF) indicated quantitative labeling of both DNA strands with the substituent (see also appendix 7-11). Yet, the primer extension assay performed with labeled DNA (2b) and TALE_Pap2_NI protein did not exhibit differential binding of TALE protein (see figure 22). The TALE does not discriminate between DNA containing adenine or the 2b-labeled nucleobase. This result suggests that the larger alkyne substituent is tolerated and well accommodated by TALEs even when the label is present in both DNA strands (see appendix 11). Models of this scenario indicate that the substituent can arrange and thread facing the open half of the groove towards the surface of the TALE-DNA complex. Furthermore, the model exhibits the possibility that even larger

substituents could be accommodated by TALEs when connected via the terminal alkyne moiety of **1b**.

Figure 22: Binding of TALE_Pap2_NI to larger substituents. **A:** Analysis of DNA oligonucleotides by ESI-TOF. The first spectrum shows the Pap2 DNA without labeling followed by labeling reaction resulting in **2a** and **2b** (from left to right), s = sense strand, a = antisense strand. Masses: s calc: 14977.8, s found: 14977.9; a calc: 15162.8, a found: 15163.9; **2b:** s calc: 15082.8, s found: 15083; a calc: 15267.8, a found: 15268; **2c:** s calc: 15713.1, s found: 15714; a calc: 15898.1, a found: 15898.7. **B:** Quantification and analysis of TALE_Pap2_NI binding to DNA with or without substituents **2b** and **2c**. The TALE-DNA ratio was 60:1 (n=3). **C:** Superimposed models of TALE_Pap2_NI interacting with DNA either containing two adenines or **2a** in each strand. The substituent **2a** is positioned opposite the RVD NI in the sense strand (green sticks) as well as in the antisense strand embedded in the palindromic GATC motif (yellow sticks). **D:** Same superimposed model as in **C** but with differently orientated surface presentation. See also appendix 8 and 9.

Based on the information of the modeling that the TALEs could accept even larger groups, the labeling reaction was repeated with the bulkier cofactor **1c**. This cofactor is derived from the molecule **1b** and extended by a tetramethylrhodamin (TAMRA) fluorophore via the Cu(I)-catalyzed [3+2] azide-alkyne cycloaddition (see figure 21/1c). Analysis by ESI-TOF reported a successful labeling reaction but with reduced yield compared to **1b** (see appendix 11). Nonetheless, primer extension again did not show any distinction in TALE_Pap2_NI binding

to either DNA containing A or 2c nucleobase. This finding implies that the bulky TAMRA group of 2c is exposed to the surface of the complex and that the N⁶ position is a blind spot for larger substituents. The N⁶-adenine position holds the possibility for even larger fluorophore labels to be tolerated by TALE proteins (see figure 23).

Figure 23: Model of TALE-Pap2_NI binding to DNA comprising substituents of the N⁶-adenine position. The TALE protein is targeting DNA towards the major groove. Substitution of the N⁶-methyl group by bulkier substituents still allows accommodation by the RVD NI. Even larger groups as a dialkynyl substituent and expanded fluorophore dye like TAMRA can be accepted by TALEs at this site. The bulky substituents are exposed to the surface of the TALE-DNA complex. Image from ⁷⁷.

4. Summary and Outlook

TALE proteins are DNA binding proteins and useful tools for genome targeting and engineering approaches. TALEs represent convenient, programmable tools to target DNA for *in vivo* and *in vitro* applications. These proteins exhibit a high flexibility which is based on their framework of modular repeats. TALEs consist of multiple concatenated repeats which are highly conserved but harbor a variable part (RVD). Each RVD enables the selective recognition of one DNA nucleobase and stabilizes the interaction between DNA target and TALE protein. Each TALE can be assembled in the lab which makes the proteins versatile, effective targeting tools. However, knowledge is required about their binding behavior to DNA, especially if the target sequence comprises epigenetically modified nucleobases. Earlier studies reported methylation sensitive TALEs of 5-methyl cytosine and many approaches were developed to overcome this sensibility or to utilize it as effective sensory tools.^{12,32,89,93} However, apart from epigenetic 5-methyl cytosine and its higher oxidized derivatives, the binding ability of TALE proteins to DNA containing the epigenetic mark of N⁶-methyl adenine (6mA) was unknown. To shed light on this, we examined the binding of TALEs to the 6mA. This epigenetic mark is predominantly found in prokaryotic genomes but was recently reported to be present in eukaryotic organisms. In this work, we find that the naturally occurring RVD NI, which recognizes the DNA nucleobase A, is not sensitive towards 6mA. Model-assisted studies with RVD variants generating more hydrophobic surfaces and the disposition for hydrogen bonding to the N⁶-amino group or N⁷-atom of adenine showed that 6mA is well accommodated by the RVD mutants. Based on the modelling results, it was suggested that even larger groups at the N⁶-position could be tolerated. Therefore, we used bulky N⁶-alkynyl-substituents which can be transferred to the GATC motif by the Dam enzyme. These substituents can be utilized and extended for even larger groups like rhodamine dyes by simple click chemistry reaction. And indeed, TALEs can also accommodate bulky N⁶-substitutions. Taken together, we report the first TALE binding studies to the epigenetic base of 6mA and its bulky substituents. Unlike cytosine and 5mC, 6mA is well tolerated by natural and modified RVDs and therefore, 6mA likely does not interfere in TALE based targeting approaches. In conclusion, these findings report the N⁶-position of adenine as a blind spot for TALE proteins which allows the introduction of labels without interferences. These results allow valuable insights for

prospective approaches using TALEs and expand their scope of application as capture probes with labeled DNA.

As complementary approach, the identification of further RVD variants, which could recognize 6mA, could deliver further insights into the TALE DNA interaction. Libraries containing RVDs with mutations of the amino acid alphabet at position 13 might identify 6mA methylation sensitive TALE RVDs.¹⁰² Also, structure-function studies on the repeat loop could deliver further information about TALEs interacting with N⁶-substituents and other potential DNA fluorophores.⁹² Consequently, these finding could be expanded to other DNA contexts, which hold for example the epigenetic mark N⁴-methyl cytosine, which like 6mA, is predominantly found in prokaryotic genomes. Furthermore, crystal structures of TALEs interacting with epigenetically modified DNA could support recent findings. With these approaches, further insights to TALEs interacting with epigenetic bases could be illuminated and used as useful knowledge for TALE construction, smart design of fluorescently labeled DNA as well as targeting and engineering approaches.

5. Zusammenfassung und Ausblick

TALE Proteine sind DNA bindende Proteine und sind ein nützliches Werkzeug für biologische Anwendungen, wie zum Beispiel die gezielte Einführung von Modifikationen im Genom einer Zelle. TALEs stellen ein günstiges, programmierbares Instrument dar, mit welchem DNA-Sequenzen in Experimenten genau angesteuert werden können. Diese Anwendung ist für *in vivo* und *in vitro* Versuchen möglich. TALE Proteine besitzen eine sehr hohe Flexibilität, welche auf einem Gerüst von sogenannten Repeat-Modulen basiert. Diese Proteine bestehen aus mehreren miteinander verketteten Repeats, welche hoch konserviert sind, jedoch einen variablen Bereich besitzen (RVD). Jeder dieser variablen Bereiche ermöglicht die selektive Erkennung von DNA Nukleinbasen und stabilisiert zusätzlich die Interaktion zwischen DNA und TALE Protein. Der modulare Aufbau der TALEs erlaubt die einfache Assemblierung dieser Proteine im Labor womit zahlreiche und vielfältige Anwendungen durchgeführt werden können. Jedoch setzt dies Wissen über das Bindevverhalten der TALE Proteine zur DNA voraus, insbesondere wenn die Zielsequenz epigenetische Modifizierungen beinhalten könnte. Frühere Studien berichten über 5-Methyl-Cytosin-sensitive TALEs und es wurden zahlreiche Ansätze entwickelt diese Sensitivität zu umgehen oder sie als sensorisches Werkzeug zu nutzen.^{12,32,89,93} Jedoch ist bisher nicht bekannt, abgesehen von 5-Methyl-Cytosin (5mC) und seinen oxidierten Derivaten, wie TALE Proteine and DNA bindet, die die epigenetische Base N⁶-Methyl-Adenosin (6mA) in seiner Sequenz trägt. Um dies zu beleuchten, untersuchten wir die Bindung von TALEs mit 6mA. Dieses epigenetische Signal kommt hauptsächlich in prokaryotischen Genomen vor, jedoch wurde es kürzlich auch in eukaryotischen Organismen nachgewiesen.^{51,54–56,103} In dieser Arbeit wird berichtet, dass das natürlich vorkommende RVD NI, welches die Nukleinbase Adenosin erkennt, nicht sensitiv gegenüber 6mA ist. Modelbasierte Studien mit verschiedenen RVD Varianten, welche eine hydrophobere Oberfläche oder H-Brückenbildung zur N⁶-Gruppe oder dem N⁷-Atom ermöglichen könnten, zeigten, dass 6mA von den RVDs durch kleinere konformative Änderungen innerhalb des TALE Proteins akzeptiert werden kann. Es erschien möglich, dass sogar größere Gruppen an der N⁶-Position durch die RVDs beherbergt werden könnte. Daher wurden in weiteren Experimenten größere N⁶-Alkynyl-Substituenten an die entsprechende Position angebracht. Ein Vorteil dieser Substituenten ist, dass diese von der Dam Methyltransferase akzeptiert werden und auf das GATC Sequenzmotiv übertragen werden können. Diese Substituenten können durch Click-

Chemie mit zusätzlichen Gruppen, wie beispielsweise Rhodamin Farbstoffen, erweitert werden. Tatsächlich binden TALE Proteine auch an DNA, welche diese größeren N⁶-Gruppen trägt. Im Gegensatz zu 5mC, kann 6mA von natürlichen und modifizierten RVDs beherbergt werden und zeigt vermutlich keinen Einfluss auf die TALE Bindung zur DNA. Diese Ergebnisse zeigen, dass die N⁶-Position als ein blinder Punkt für TALE Proteine sein könnte, welcher die Einführung von Labeln ohne Einflussnahme auf die Protein-DNA Bindung erlaubt. Diese Ergebnisse erlauben wertvolle Einblicke für weitere TALE Anwendungen und erweitern den Einsatzumfang von TALE Proteinen mit markierter DNA.

Komplementäre Ansätze zur Identifizierung von 6mA-sensitiven RVD Varianten könnten die Einblicke in die TALE-DNA Interaktion vertiefen. Die Generierung von RVD-Bibliotheken, welche Mutationen des gesamten Aminosäuren-Alphabetes and Position 13 tragen, könnte 6mA-bindende RVD Varianten zu Tage befördern.¹⁰² Des Weiteren könnten weitere Struktur-Funktions-Studien über die Repeat-Schleife weitere Informationen über TALEs, die mit größeren N⁶-Gruppen und potentiellen Fluorophoren interagieren, liefern.⁹² Diese Ergebnisse könnten auf andere DNA-Sequenzkontexte erweitert werden, welche beispielsweise die epigenetische Modifikation N⁴-Methyl-Cytosin beinhalten, die wie 6mA überwiegend in prokaryotischen Genomen vorkommt. Außerdem könnte die Erzeugung von Kristallstrukturen von TALEs in Interaktion mit epigenetischen Basen bisherige Ergebnisse unterstützen und möglicherweise weitere Einblicke liefern. Diese Ergebnisse und Ansätze können verwendet werden für die Generierung von TALE Proteinen, sowie das smarte Design von Fluorophor-markierter DNA.

6. Materials and Methods

6.1 Materials

6.1.1 Oligonucleotides

DNA oligonucleotides were purchased from Sigma-Aldrich (0.025 μ mol scale, purified by desalting) or from Metabion for methylated oligos (A). Oligonucleotides were stocked as 100 μ M solutions in water. Working concentration of primers were adjusted to 10 μ M.

6.1.5 Media

Table. 8: Overview of media used for optimal growth of *E. coli*.

| Type of Media | Chemical | Concentration |
|--|-------------------|---------------|
| LB-medium (Lysogeny Broth) (pH = 7.0) | Tryptone | 10 g/L |
| | Yeast extract | 5 g/L |
| | NaCl | 5 g /L |
| LB-agar (pH = 7.0) | Tryptone | 10 g/L |
| | Yeast extract | 5 g/L |
| | NaCl | 5 g/L |
| | Agar-Agar | 15 g/L |
| SOC-medium (pH = 7.0) | Tryptone | 2 % (w/v) |
| | Yeast extract | 0.5 % (w/v) |
| | NaCl | 10 mM |
| | KCl | 2.5 mM |
| | MgCl ₂ | 10 mM |
| | MgSO ₄ | 10 mM |
| | Glucose | 20 mM |

6.1.6 Buffers

6.1.6.1 Buffers for Protein Purification

Table 9: Buffers for native purification of TALE proteins with GFP-tag.

| Native purification | Chemicals | Concentration |
|---|----------------------------------|---------------|
| Qiagen lysis buffer (pH = 8.0) | NaH ₂ PO ₄ | 50 mM |
| | NaCl | 300 mM |
| Qiagen wash buffer 1 20 mM Imidazole (pH = 8.0) | NaH ₂ PO ₄ | 50 mM |
| | NaCl | 300 mM |
| | Imidazole | 20 mM |
| Qiagen wash buffer 2 50 mM Imidazole (pH = 8.0) | NaH ₂ PO ₄ | 50 mM |
| | NaCl | 300 mM |
| | Imidazole | 50 mM |
| Qiagen elution buffer 500 mM Imidazole (pH = 8.0) | NaH ₂ PO ₄ | 50 mM |
| | NaCl | 300 mM |
| | Imidazole | 500 mM |
| PBS (4x) (pH = 8.0) | NaCl | 548 mM |
| | KCl | 43 mM |
| | Na ₂ HPO ₄ | 69 mM |
| | KH ₂ PO ₄ | 24 mM |

Table 10: Buffers for denaturing workup of TALE proteins with TRX-tag.

| Native purification | Chemicals | Concentration |
|---------------------------------------|----------------------------------|---------------|
| Taq lysis buffer (pH = 9.0) | Tris*HCl | 100 mM |
| | NaCl | 300 mM |
| | MgCl ₂ | 2.5 mM |
| | TritonX-100 | 0.1 % (v/v) |
| Buffer-Z wash buffer 1 (pH = 8.0) | Urea | 8 M |
| | NaCl | 100 mM |
| | Hepes | 20 mM |
| | Imidazole | 20 mM |
| Buffer-Z wash buffer 2 (pH = 8.0) | Urea | 8 M |
| | NaCl | 100 mM |
| | Hepes | 20 mM |
| | Imidazole | 50 mM |
| Buffer-Z elution buffer (pH = 8.0) | Urea | 8 M |
| | NaCl | 100 mM |
| | Hepes | 20 mM |
| | Imidazole | 500 mM |
| PBS (4 x) (pH = 8.0) | NaCl | 548 mM |
| | KCl | 43 mM |
| | Na ₂ HPO ₄ | 69 mM |
| | KH ₂ PO ₄ | 24 mM |

6.1.6.2 Buffer for Dialysis of TALE Proteins

Table 11: Overview of used dialysis buffers.

| Dialysis buffer | Chemicals | Concentration |
|---------------------------------------|------------------------------|------------------------------|
| 5 x TALE storage buffer (pH = 7.5) | Tris*HCl NaCl Glycerol | 100 mM 1 mM 50 % (v/v) |

6.1.6.3 Reaction Buffers

Table 12: Reaction buffers for Primer Extension.

| Primer Extension | Chemicals | Concentration |
|---------------------------------------|---|--|
| 5 x TALE storage buffer (pH = 7.5) | Tris*HCl NaCl Glycerol | 100 mM 1 mM 50 % (v/v) |
| 5 x TALE binding buffer | Tris*HCl (pH = 8) NaCl MgCl ₂ BSA Glycerol | 100 mM 250 mM 25 mM 0.5 mg/ml 50 % (v/v) |
| KF storage buffer | Tris*HCL (pH = 7.5) EDTA DTT Glycerol | 25 mM 0.1 mM 1 mM 50 % (v/v) |

Table 13: Reaction buffers for EMSA.

| EMSA | Chemicals | Concentration |
|-------------------------|--|---------------------------|
| 5 x BGrK1 (pH = 7.5) | Tris*HCl (pH = 8) NaCl MgCl ₂ | 100 mM 250 mM 25 mM |

Table 14: Reaction buffers for alkylation by Dam methyltransferase.

| Alkylation | Chemicals | Concentration |
|--|-------------------|---------------|
| Dam reaction buffer (10 x) (pH = 8) | Tris*HCl (pH = 8) | 1500 mM |
| | EDTA | 100 mM |
| | DTT | 20 mM |
| Dam storage buffer (pH = 7.5) | Tris*HCl | 50 mM |
| | KCl | 50 mM |
| | EDTA | 10 mM |
| | DTT | 1 mM |
| | Glycerol | 52.5 % (v/v) |

6.1.6.4 Buffers for Gel-Electrophoresis

Table 15: Buffers and gel composition for denaturing PAGE.

| Denaturing PAGE | Chemicals | Concentration |
|-------------------------------|----------------------------|---------------|
| TBE running buffer (10 x) | Tris*HCl | 890 mM |
| | Boric Acid | 890 mM |
| | EDTA | 20 mM |
| TBE running buffer/Urea | Tris*HCl | 890 mM |
| | Urea | 9 M |
| | Boric Acid | 890 mM |
| | EDTA | 20 mM |
| Denaturing PAGE gel (10 %) | Sequencing gel concentrate | 40 ml |
| | 10 x TB / 9 M urea | 10 ml |
| | 9 M urea | 50 ml |
| | APS (10 % w/v) | 800 µl |
| | TEMED | 40 µl |
| Denaturing loading buffer | Formamide | 80 % (v/v) |
| | EDTA | 2 mM |
| | Bromophenol blue | 1 g |

Table 16: Buffers and gel composition for EMSA.

| EMSA | Chemicals | Concentration |
|-----------------|-------------------------|---------------|

6.2 Methods

6.2.1 General Biomolecular Methods

6.2.1.1 Preparation of Chemically Competent Cells

20 ml of LB-media was inoculated with a single *E. coli* colony picked from an agar plate. The culture was incubated at 37°C overnight shaking at 180 rpm. The next day, 800 ml of LB-medium was inoculated with 8 ml of the overnight culture. The culture was incubated at 37°C until the OD_{600 nm} of 0.4 was reached. The culture was cooled on ice and equally distributed to 16 flacon tubes (50 ml). Cells were harvested by centrifugation at 4000 rpm at 4°C for 10 min. The supernatant was discarded and the pellet were resuspended in 10 ml MgCl₂ buffer. The cell suspension was centrifuged again and the remaining pellets were resuspended in 10 ml CaCl₂ buffer. The bacterial suspension was incubated for 30 min on ice and again centrifuged at 4°C, 4000 rpm for 10 min. The supernatant was discarded and the pellets were pooled and resuspended in an overall volume of 4 ml storage buffer. The cell suspension was aliquoted and snap frozen with liquid nitrogen. The cells were stored at -80°C.

6.2.1.2 Transformation of Chemically Competent Cells

About 10 to 100 ng of plasmid solution was mixed with 50 µl of chemically competent *E. coli* cells (50 µl aliquot). The suspension was mixed carefully by stirring with a pipette tip and incubated on ice for 30 min. Then, the cells were heat shocked at 42°C for 30 seconds, incubated again on ice for 2 min. The cells were rescued with 1 ml pre-warmed SOC by incubation at 37°C for 1 h (1000 rpm shaking). After incubation, the cells were plated on LB-agar plated supplied with the respective antibiotic and incubated at 37°C overnight.

6.2.1.3 Isolation of Plasmids

For isolation of plasmids, 5 ml of LB-media was inoculated with a single colony picked from an agar plated. The culture was supplied with the respective antibiotic and incubated at 37°C overnight. The next day, the culture was pelleted by centrifugation at 4000 rpm for 10 min and the supernatant was discarded. The pellet was resuspended in 250 µl of resuspension buffer and transferred to a 1.5 Eppendorf tube following the manufacturers protocol (GenJET

plasmid Minprep Kit, Qiagen). Then, 250 μ l lysis solution were added and the tubes were inverted several times followed by addition of neutralization buffer and repeated inversion. After centrifugation for 5 min at 1400 rpm the supernatant was isolated from the cell debris and transferred to the supplied columns. After centrifugation for 1 min, 500 μ l of washing buffer was added and the flow through was discarded. The columns were centrifuged for 1 min to remove remaining washing buffer. Finally, the columns were placed in a new 1.5 ml Eppendorf tube and air dried to remove residual ethanol. 50 μ l of MilliQ-H₂O were added to the column and the plasmids were eluted by centrifugation at 14000 rpm for 2 min.

6.2.1.4 Sanger Sequencing of DNA

5 μ l of 30-75 ng of DNA, 2.5 μ l of respective primers (2.5 μ M) and 2.5 μ l of MilliQ-H₂O were mixed and sent for sequencing in a 1.5 ml Eppendorf tube to GATC biotech company. Sequence traces were analyzed using Finch TV software and aligned to theoretical sequences using Serial Cloner software.

6.2.1.5 Agarose Gel-Electrophoresis

Agarose powder was resuspended in 0.5 x TBE buffer and heated in a microwave until it was completely dissolved. The solution was cooled to approximately 40°C and then poured into a gel casting tray. A comb was placed on top and the polymerized gel was transferred to a gel chamber filled with 0.5 x TBE buffer. Prepared DNA samples were mixed with DNA loading dye and carefully loaded onto the gel. The gel was run for 1 h at 120 V or adjusted conditions for higher resolution. The gel was incubated in an aqueous ethidium bromide solution for 5 min and destained in MilliQ-H₂O. The gel was put on a Biometra UV-table (254 nm) and the image was collected by a gel documentation system. If necessary, DNA fragments could be extracted from the agarose gel by excising the fragment from the gel with a scalpel followed by use of GenJET gel extraction kit (Qiagen).

6.2.2 Cloning and Modification of Plasmids

6.2.2.1 Site Directed Mutagenesis

For introduction of site-directed mutagenesis of TALE module plasmids (repeat position 13) primers were designed following the guidelines from Agilent for QuikChange site directed mutagenesis. Forward and reverse primers exhibit melting temperatures of $\geq 78^{\circ}\text{C}$, a GC content above 40 % and the ends should possibly contain a G or C. The lengths of the primers varied to match the required melting temperatures, but were commonly between 30 to 45 bp. The desired mutational site should be placed in the middle part of the sequence with 15 to 20 bp flanking it.

The reaction was performed in a total volume of 25 μl . The reaction mix contained 10 to 50 ng template plasmid, 200 μM dNTPs, 200 nM forward and reverse primers, as well as Pfu Ultra DNA polymerase and its respective reaction buffer. The reaction was carried out with an initial denaturation step for 30 s at 95°C , followed by 16 cycles of 30 s at 95°C , annealing for 60 s at 55°C and elongation at 60 s per kb at 68°C . The final elongation was conducted at 68°C for 7 min followed by storage of the reaction at 4°C . Subsequently, the reaction was digested with *DpnI* (0.5 μl , 10 U) at 37°C for 1 h. Without further purification, 4 μl were transformed into 50 μl of chemically competent *E. coli* GH371 cells. Clones were isolated and checked for correct mutagenesis by Sanger sequencing.

6.2.2.2 TALE Assembly

TALE plasmids were assembled according to a two-step Golden Gate protocol published by Cermak et al in 2011⁹⁷. The module repeat plasmids were assembled according to the desired RVD sequence using the module plasmids numbered in that order. The first intermediate array called pFUS_A can include up to 10 repeat modules. The next repeat modules are cloned into a second array pFUS_B (see figure 24). In the first Golden Gate reaction, the single module plasmids as well as the backbone intermediate arrays are subjected to digestion by *BsaI* enzyme at 37°C for 5 min followed by ligation with T4 DNA ligase at 16°C for 10 min. The reaction is incubated for 10 to 15 cycles, then heated to 50°C for 5 min and terminated at 80°C for 5 min. 0.5 μl of ATP (25 mM stock) and 0.5 μl of plasmid safe nuclease are added to the 25 μl reaction and incubated at 37°C for 1 h. Eventually, the reaction was heat inactivated

by incubation at 70°C for 20 min. Approximately 4 µl of this reaction mix was transformed into *E. coli* GH371 cells without any further purification steps. Positive clones could be pre-selected by a blue-white screening if XGal (5-bromo-4-chloro-3-indolyl-β-D-galactopyranoside) was added to the plates. Up to 4 white clones were picked for further analysis by colony PCR. Therefore, 1 µl of the respective bacterial suspension was diluted to a 25 µl reaction volume supplemented with 250 µM dNTPs, 100 nM of forward and reverse primes oSaB374/oSaB375, 40 mU Taq polymerase and thermo pol buffer. The reaction mix was incubated at 94°C for 2 min, followed by 35 cycles of 94°C, 55°C 30 s, 68°C 2 min and a final extension step at 68°C for 2 min. The results of the colony PCR were monitored on a 1 % agarose gel for correct size. If the clones were identified with the correct size, 5 ml of overnight cultures supplied with spectinomycin were inoculated with the respective bacterial suspension. 1 µl of each bacterial suspension was spotted to a safe plate.

Figure 24: First step of Golden Gate assembly of TALE protein. The module plasmids are arranged according to the sequence of interest and assembled to an array plasmid via a restriction and ligation reaction. Adapted from 97

The next day, plasmids were isolated and subjected to Golden Gate 2 reaction. In this reaction, the intermediate arrays pFUS_A and pFUS_B, along with the last repeat and the backbone vector pET_TRX_ENTRY or pET_GFP_ENTRY are joined (see figure 25). A 10 µl digestion with *BsmBI* restriction enzyme and ligation reaction mixture is prepared as in the

first step (10 cycles). Plasmid safe treatment was omitted in this step. About 4 μ l of the reaction was transformed into expression strain *E. coli* BL21 (DE3). The transformed cells were plated on LB-agar plates supplemented with carbenicillin. The next day 4 white colonies were picked and monitored by colony PCR (primers oSaB890/oDaS247). If the size was correct, 5 ml of LB-media cultures were inoculated with the respective bacterial suspension and incubated at 37°C overnight. The next day the plasmids were isolated and sent for sanger sequencing to check for correct sequence using sequencing primers oDaS315, oSaB890 and oDaS247.

Figure 25: Second step of Golden Gate assembly of TALE protein. Each array plasmid can hold up to 10 repeat modules. Consequently, the array repeats and the last repeat are joined in a second restriction and ligation reaction and connected to the backbone vector, which holds the N-terminal and C-terminal domains of the protein. Adapted from ⁹⁷.

6.2.3 Expression and Purification

6.2.3.1 Expression and Purification of TALE Proteins with TRX-Tag

Single clones of *E. coli* BL21 (DE3) Gold transformed with TALE expression plasmids (pSaB339_pET_TRX_final_entry) picked and 5 ml LB-media supplemented with 50 µg/ml carbenicillin was inoculated. The culture was incubated at 37°C overnight. The next day, the overnight cultures were diluted 40-fold into LB-medium supplemented with carbenicillin. The culture was grown at 37°C and 250 rpm shaking until an OD_{600 nm} of 0.4 was reached and induced with a final concentration of 0.2 mM IPTG. After 5 h of incubation, expression culture was harvested by centrifugation (15 min, 4000 rpm, 4°C). The supernatant was discarded and the remaining pellet was lysed in Taq lysis-buffer supplied with 1 mM PMSF and 50 µg/ml lysozyme by shaking at room temperature at 1400 rpm for 30 min. The suspension was pelleted by centrifugation (20 min, 9000 rpm, 4°C) and the supernatant was discarded. Under denaturing conditions, the TALE protein was extracted from the pellet and bound to Ni-NTA resin according to the manufactures protocol. The resin was washed two times with 4 x PBS-buffer four times with washing buffer 1 containing 20 mM imidazole and once with washing buffer 2 with 50 mM imidazole. Finally, the protein was eluted from the column with elution buffer containing 500 mM imidazole. The respective fractions were pooled and monitored by SDS-PAGE.

6.2.3.2 Expression and Purification of TALE Proteins with GFP-Tag

Single clones of *E. coli* BL21 (DE3) Gold transformed with TALE expression plasmids based on pET_GFP_final_entry (pAnI521) and expressed as described above. After 5 h of expression the cultures were harvested by centrifugation (15 min, 4000 rpm, 4°C). The remaining pellets were lysed in Qiagen lysis buffer containing 1 mM PMSF and 50 µg/ml lysozyme and additionally disrupted using French press. Then, the solution was centrifuged (15 min, 9.000 rpm, 4°C), the supernatant was collected and extracted with Ni-NTA). For purification, the same procedure was applied as described for TRX-TALEs above.

6.2.3.3 SDS-PAGE

TALE proteins were monitored on 8 % SDS-PAGE gels. Proteins were analyzed on 8 % SDS-gels by PAGE. The resolving gel was prepared from 3808 µl MilliQ-water, 1092 µl Acrylamide

concentrate (40 %), 420 µl Tris (pH = 8.8), 66.7 µl SDS solution (10 %), 66.7 µl APS solution (10 %) and 6.67 µl TEMED. After 30 min of polymerization, the stacking gel prepared from 1000 µl MilliQ-water, 208 µl Acrylamide concentrate, 420 µl Tris (pH = 6.8), 16.7 µl SDS solution, 16.7 µl APS solution and 1.67 µl TEMED was poured onto the resolving gel. Protein samples were mixed with 10 µl of SDS-PAGE loading buffer and denatured at 95°C for 5 min. Subsequently, 15 µl of the samples were loaded onto the gel. The gel was run at 120 V for 1.5 h. Finally, after staining the gel with brilliant blue solution for about 30 to 60 min, the gel was destained and the image of the gel was documented.

6.2.3.4 Dialysis and Storage of TALE Proteins

The TALE proteins were placed into dialysis tubes (molecular weight cut off 10 kDa) and dialyzed against 1 x TALE storage buffer at 4°C. The buffer was changed several times until the concentration of imidazole from the elution buffer was diluted to a picomolar range. The purity of the TALE proteins was controlled by SDS-PAGE. Quantification of the protein concentration was performed with BCA assay (Thermo Fisher, compatible with DTT reducing agent) followed by snap freezing of 20 µl aliquots and long-term storage at -80°C.

6.2.4 Enzymatic Alkylation of DNA Duplexes by Dam Methyltransferase

Oligonucleotide pairs oSaB900/oSaF1815 and oSaB874/oSaF1815 were hybridized in 15.5 µl Dam reaction buffer by incubation mix at 95°C for 5 min. The hybridization was then allowed to room temperature for 30 min. SAM analogues were added (80 µM final concentration) and the pH was adjusted to 8.0 if necessary. After addition of 0.5 µl *E. coli* Dam enzyme (51.5 µM stock, 1.65 µg/ml) the reaction was incubated at 37 °C for 4 h in a final reaction volume of 312.5 µl. The reaction mix was then purified with a PCR cleanup kit (Qiagen) and the amount of DNA was quantified by UV absorption measurement. The reaction was checked for correct alkylation by sending samples to Metabion international AG to perform ESI-TOF mass spectrometry.

6.2.5 Primer Extension

Oligonucleotides o875 and o770 were ³²P-radiolabeled at the 5'-end using [gamma]-³²P-ATP and T4 polynucleotide kinase. The labeled oligos were purified by G-25 gel filtration. The template oligonucleotides and radiolabeled primers (oSAB900/oSaB874, oSaB899/oSaB873) were diluted to 6 µl of hybridization buffer and incubated at 95°C for 5 min. The hybridization mix (was then allowed to cool to room temperature for 30 min. 6 µl of varying concentrations of TALE protein diluted in 1 x TALE storage buffer were added to the hybridization mix and incubated for another 30 min at room temperature. 12 µl of Klenow Fragment *E. coli* DNA polymerase (30 mU, 3'-5' exo-) were added to the reaction resulting in a final concentration of 8.325 nM and 25 nM for primer and template, respectively. The reaction was incubated for 15 min, then stopped with addition of 12 µl of PAGE loading buffer and incubation at 95°C for 5 min. The samples were loaded onto a pre-run denaturing PAGE gel (9 M urea) and it was run in 1 x TBE buffer at 120 W for 1 h. Then, the gel was transferred to Whatman paper and covered with cling film. The gels were dried for a minimum of 1 h and a phosphor plate was exposed to it overnight. The next the image of the gel was collected by a phosphor imager and analyzed by ImageJ/Quantity One software.

6.2.6 Electromobility Shift Assay

Oligonucleotide pairs oSaB900/oSaF1815 and oSaB874/oSaF1815 were incubated at 95°C for 5 min in 1 x BGrK1 buffer. After hybridization of the oligos, the samples were cooled to room temperature for 30 min. 1.5 pmol of TALE protein with N-terminal GFP domain was incubated with varying concentrations of DNA (2.5 pmol – 0.5 pmol) at room temperature for 30 min and additional 30 min on ice. The reaction was carried out in 1 x BGrK1 buffer resulting in a final volume of 10 µL. 5 µl of the reaction mix were loaded onto a pre-run EMSA gel and run with 70 V for 90 min at 4 °C. The GFP-fluorescence of the TALE-proteins was recorded with a Typhoon FLA-9500 laser scanner and TALE-DNA complexes were analyzed with ImageJ software.

Appendix 5: Amino acid sequence of TALE_Pap5 with RVD NI at position 7 and green fluorescent protein tag.

Appendix 6: SAM (AdoMet) and synthesized analogs (AdoYnYn, 1b) are accepted by the Dam enzyme (EcoDam). λ -DNA is labeled by the Dam enzyme with SAM and cofactor 1b. In the reaction mix the concentration of the labeling enzyme was varied in equivalents of enzyme in respect to GATC recognition sites. The Dam transferase is self-expressed and not purchased by a custom provider to ensure a functional, SAM-free enzyme. After the labeling reaction, the mix analyzed by restriction digest. The assay was performed by the Elmar Weinhold group, RWTH Aachen.

Appendix 7: ESI-TOF MS analysis of unmodified oligonucleotide duplex of the Pap2 sequence context (oligos o900 and o1815).

Appendix 8: Model of TALE (light brown) with the RVD NI accommodating substituent 1b.(violet) Model was generated by Julia Jasper and Oliver Koch, TU Dortmund.

Appendix 9: Model of TALE (violet) with the RVD NI accommodating substituent 1b.(orange) Model was generated by Julia Jasper and Oliver Koch, TU Dortmund.

| oligo | GATC | mass oligo [Da] | mass added by 2 [Da] | calculated mass [Da] | identified signal [m/z] | abundance [%] |
|-------|------|-----------------|----------------------|----------------------|-------------------------|---------------|
| o900 | A | 15162.75 | 105.07 | 15267.82 | 15267.98 | 100 % |
| o1815 | A | 14977.76 | 105.07 | 15082.82 | 15082.96 | 97.7 % |

Appendix 10: ESI-TOF MS analysis of N6-modified oligonucleotide duplex of the Pap2 sequence context (oligos o900 and o1815) by *E. coli* Dam methyltransferase with cofactor 1b.

Appendix 11: ESI-TOF MS analysis of N⁶-modified oligonucleotide duplex of the Pap2 sequence context (oligos o900 and o1815) by *E. coli* Dam methyltransferase with cofactor 1c.

9. Abbreviations

| | |
|----------|---|
| A | adenine |
| 6mA | N ⁶ -methyl adenine |
| 6hmA | N6-hydroxymethyl adenine (in RNA) |
| 6fA | N6-formyl adenine (in RNA) |
| AD | activation domain |
| Amp | ampicillin |
| ATP | adenosine triphosphate |
| AU | arbitrary units |
| BER | Base Excision Repair |
| bp | base pair |
| °C | degree Celsius |
| C | cytosine |
| 5mC | 5-methyl cytosine |
| 5hmC | 5-hydroxymethyl cytosine |
| 5caC | 5-carboxymethyl cytosine |
| 5fC | 5-formyl cytosine |
| N4mC | N ⁴ -methyl cytosine |
| CpG | cytosine preceding guanine dinucleotide |
| CRISPR | clustered regularly interspaced short palindromic repeats |
| CRD | central repeat domain |
| CTR | C-terminal region |
| <i>D</i> | aspartic acid |
| Dam | deoxyadenosine methyltransferase |
| DNA | deoxyribonucleic acid |
| gDNA | genomic DNA |
| DMT | DNA methyl transferase |
| dNTP | deoxy ribonucleotide triphosphate |
| ds | double stranded |
| <i>E</i> | glutamic acid |
| EMSA | electromobility shift assay |
| ESI-TOF | Electrospray ionization time of flight |

| | |
|-------|---|
| FLASH | Fast Ligation-based Automatable Solid-phase High-throughput |
| G | guanine |
| G | glycine |
| GFP | green fluorescent protein |
| GG | golden gate cloning |
| H | histidine |
| HD | RVD HD |
| His6 | histidine tag |
| I | isoleucine |
| K | lysine |
| L | leucine |
| Lrp | leucine responsive protein |
| LR | last repeat |
| meDIP | methylated DNA immunoprecipitation |
| mESC | mouse embryonic stem cells |
| min | minutes |
| ml | milliliter |
| mM | millimolar |
| mU | milliunits |
| MTase | methyltransferase |
| N | asparagine |
| NE | RVD NE |
| NG | RVD NG |
| ng | nanogram |
| NHEJ | non-homologous end joining |
| NI | RVD NI |
| NL | RVD NL |
| NLS | nuclear localization sequence |
| nM | nanomole |
| nm | nanometer |
| NN | RVD NN |
| nt | nucleotide |
| NV | RVD NV |

| | |
|-----------------|--|
| OD | optical density |
| oriC | origin of replication |
| Pap | pyelonephritis associated pili |
| PEX | primer extension |
| R | arginine |
| RM | restriction-modification |
| RNA | ribonucleic acid |
| gRNA | guiding RNA |
| rpm | revolutions per minute |
| RVD | repeat variable di-residue |
| S | serine |
| SAM | S-adenosyl methionine |
| SAH | S-adenosyl homocysteine |
| T | Thymine |
| TALEs | transcription-activation-like effector |
| TAMRA | tetramethylrhodamine |
| TET1 | ten-eleven-translocase 1 |
| TDG | thymine DNA glycosylase |
| TRX | thioredoxin |
| TSS | transcription starting site |
| UHPLC-MRM-MS/MS | ultra-high-performance liquid chromatography triple quadrupole mass spectrometry |
| UPEC | uropathogenic <i>E. coli</i> |
| V | valine |
| V | Volt |
| W | Watt |
| ZF | Zinc finger |
| µg | microgram |
| µl | microliter |
| µM | micromol |

Note: chemical abbreviations can be found in the section 6.1.8.

10. Curriculum Vitae

Personal Details

Name: Sarah Flade, M.sc.
Date of birth: 30.06.1988
Place of birth: Neuenbürg, Germany
Nationality: German

Education

Since 10/2013 **PhD student (Dr. rer. nat.)**
at the University of Konstanz and TU Dortmund
in the field of microbiological epigenetics and molecular
biology of TALE proteins. Supervision: Prof. Daniel Summerer.

10/2013 – 03/2016 **Research Scholarship**
of the Konstanz Research School Chemical Biology and fellow
of the Konstanz Graduate Program.

10/2011 - 08/2013 **Master of Science Chemical Biology**
at the Karlsruhe Institute of Technology
Master thesis: *“Structure-Activity-Relationship of the
antimicrobial and synergistic peptides PGLa and Magainin 2”*.
Supervision: Prof. Anne Ulrich.

10/2008 – 07/2011 **Bachelor of Science Biology**
at the Karlsruhe Institute of Technology
Bachelor thesis: *“Effects of ethanol on early development in
zebrafish”*. Supervision: Prof. Uwe Strähle, Universität
Heidelberg.

Publications

1. **Sarah Flade**, Julia Jasper, Mario Gieß, Maytas Juhasz, Andreas Dankers, Grzegorz Kubik, Oliver Koch, Elmar Weinhold und Daniel Summerer, "The N6-Position of Adenine is a Blind Spot for TAL-Effectors that Enables Effective Binding of Methylated and Fluorophore-Labeled DNA", *ACS Chemical Biology*, **2017**.
DOI: 10.1021/acscchembio.7b00324.

Poster Presentations

1. Sarah Flade, Julia Jasper, Maytas Juhasz, Andreas Dankers, Grzegorz Kubik, Oliver Koch, Elmar Weinhold und Daniel Summerer, *The N6-Position of Adenine is a Blind Spot for TAL-Effectors that Enables Effective Binding of Methylated and Fluorophore-Labeled DNA*, poster presented at the annual "Day of Chemistry" of the TU Dortmund, 2017, Dortmund.
2. Sarah Flade and Daniel Summerer, *Recognition and Control of Adenine-N⁶-Methylation by TALEs*, poster presented at the 7th annual retreat of the Konstanz Research School Chemical Biology, 2015, Gültstein.
3. Sarah Flade and Daniel Summerer, *Recognition of N6-Methyladenine in DNA by Transcription-activation-like effectors*, Poster presented at the 6th annual retreat of the Konstanz Research School Chemical Biology, 2014, Bad Herrenalb.
