

## “Learning from Rootkits”

- Safe Place to stand for a Runtime Monitoring/Attestation System -

*SPRING 5: SIDAR Graduierten-Workshop über Reaktive Sicherheit*

Patrick Stewin, 7. July 2010, Bonn, Germany

patrickx@sec.t-labs.tu-berlin.de

# Agenda

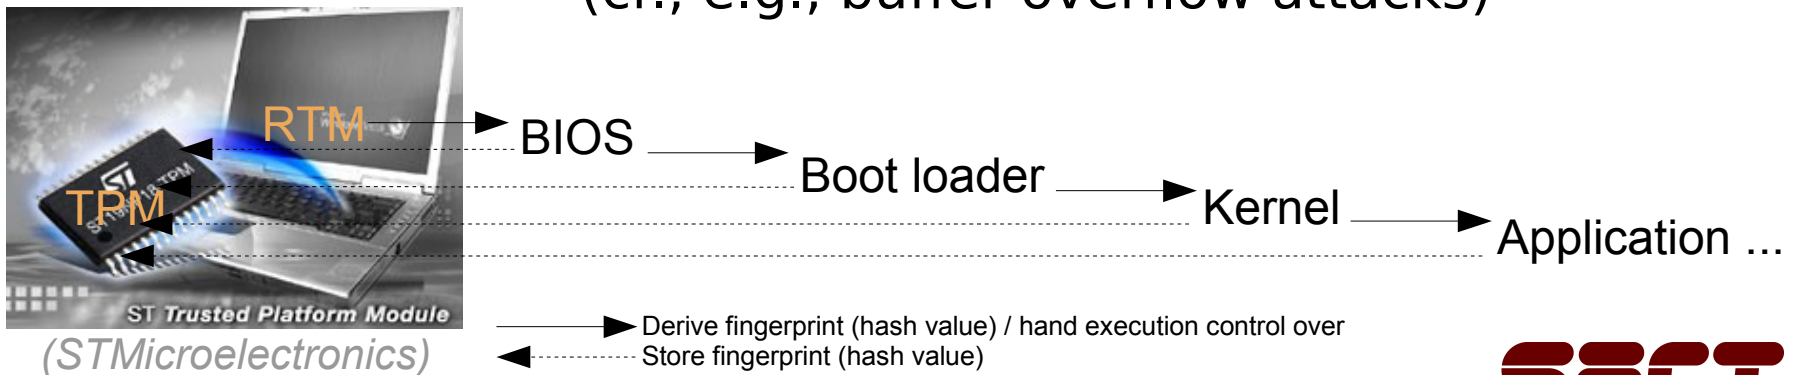

- Introduction
- Motivation
- Challenges
- Analysis x86 Platform
- Challenges for Attackers/Rootkits
- Important Related Work
- Conclusion and Further Research

# Introduction

- Rootkit evaluation:
  - Originally placed in user space with root privileges to hide it
  - Rootkits moved from user space to kernel space and beyond!
  - Goal: somehow isolate rootkit from host platform using platform's stealth capabilities
- Stealth - Isolation
- Can we use stealth/isolation capabilities of x86 platforms to improve security properties?

# Motivation

- Why to improve computer platform security properties?
- Example: Time-Of-Check-Time-Of-Use (TOCTOU) problem
  - Cf. Trusted Computing Group (TCG) attestation model
    - Chain of Trust starting at Root of Trust for Measurement (RTM)
      - Derives and stores fingerprint of software before software gets execution control
      - TOC: once, just before execution
      - No statement about runtime behavior (cf., e.g., buffer overflow attacks)

# Goals

- Understand isolated execution environments to:
  - i. Develop countermeasures against powerful and stealthy rootkits
  - ii. Use them to enhance platform's security properties

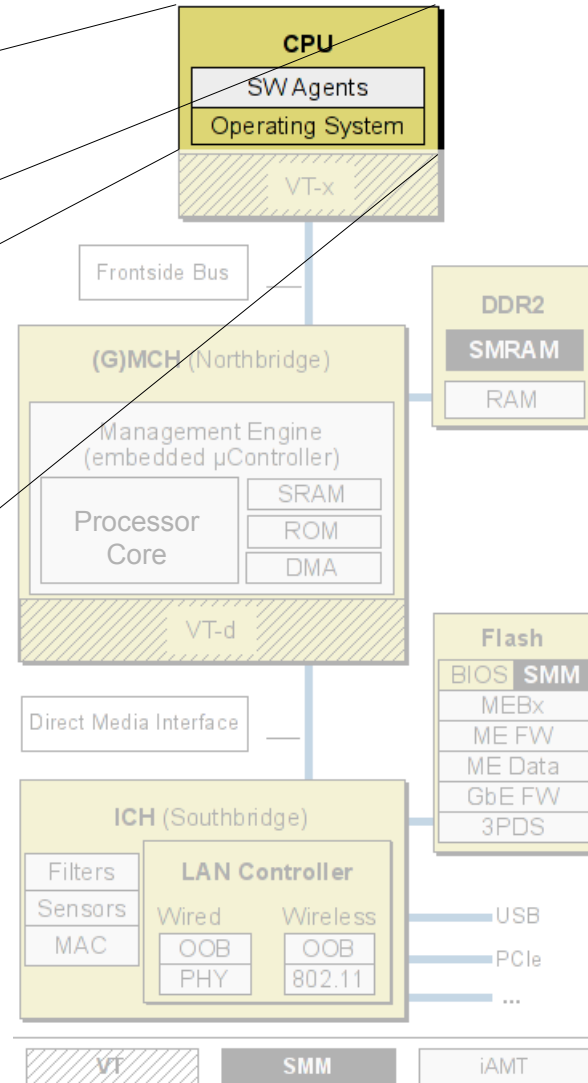

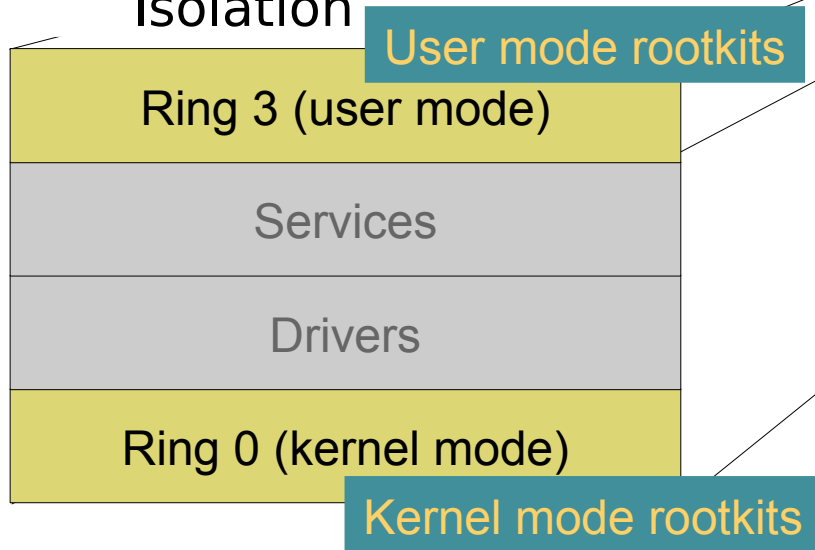

# Challenges

- Research mainly done on rootkits
- Monitor needs safe place to stand: “Learning from Rootkits”
  - Understand properties of rootkit environments
  - Related to Trusted Computing Base
- Monitor environment must be *bullet proof*
  - Rootkit environments are not!
- Measurement strategy
  - How, when and what to measure?

# Analysis of x86 Platform

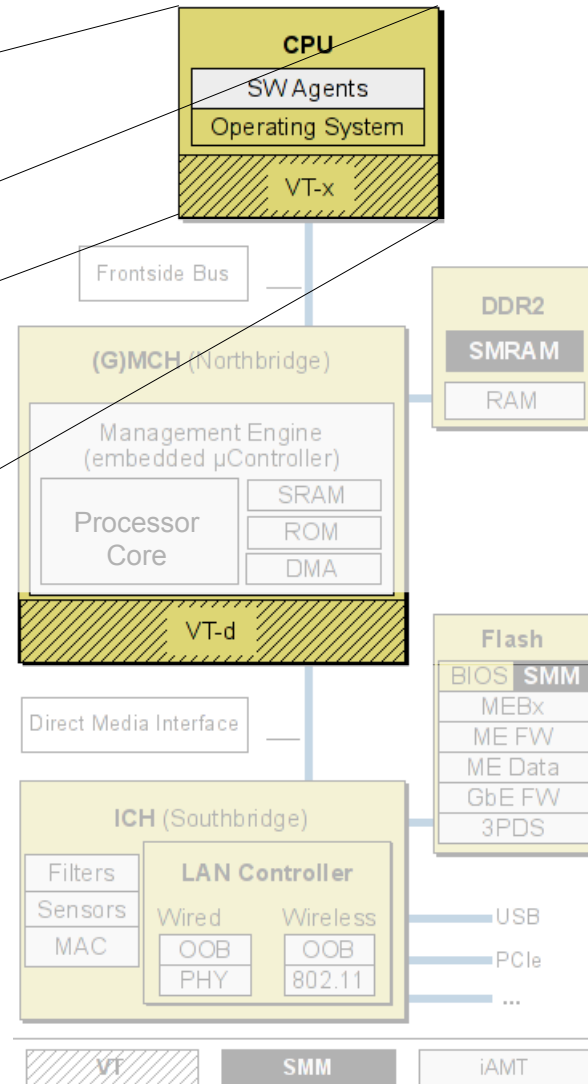

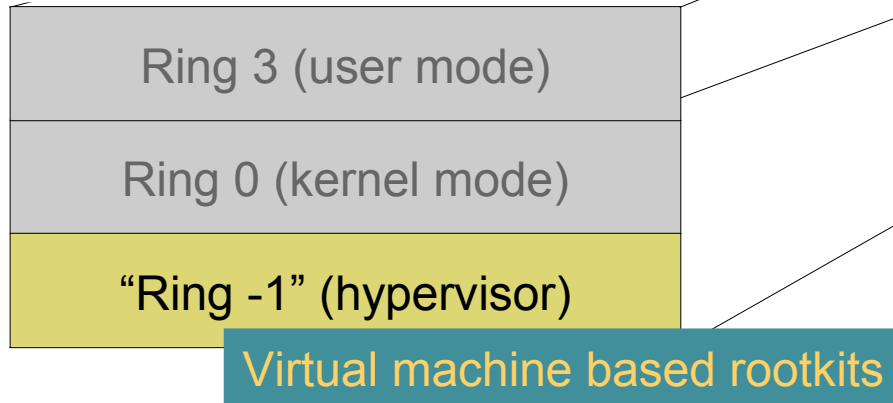

- Protected Mode**

Rings for Domain Isolation

# Analysis of x86 Platform

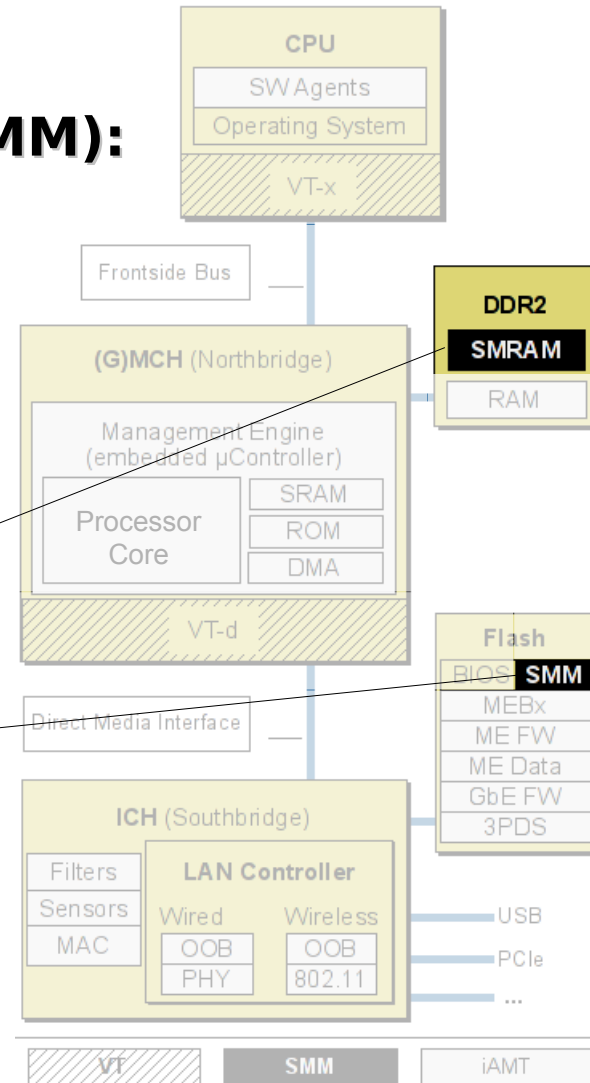

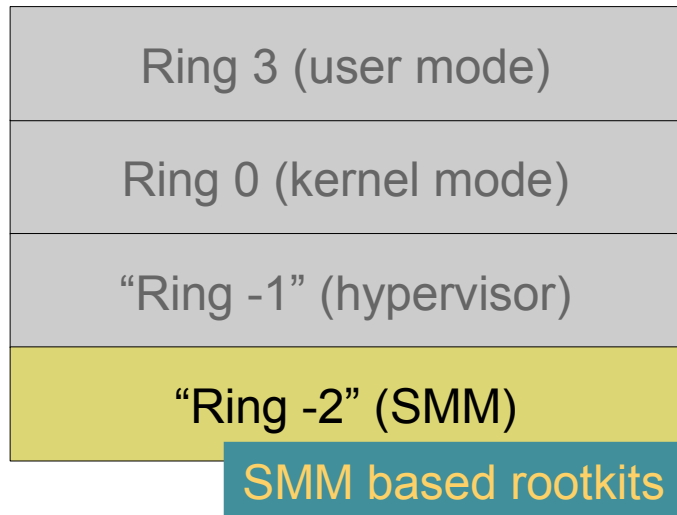

- HW Virtualization Extensions:**  
 E.g. OS Isolation

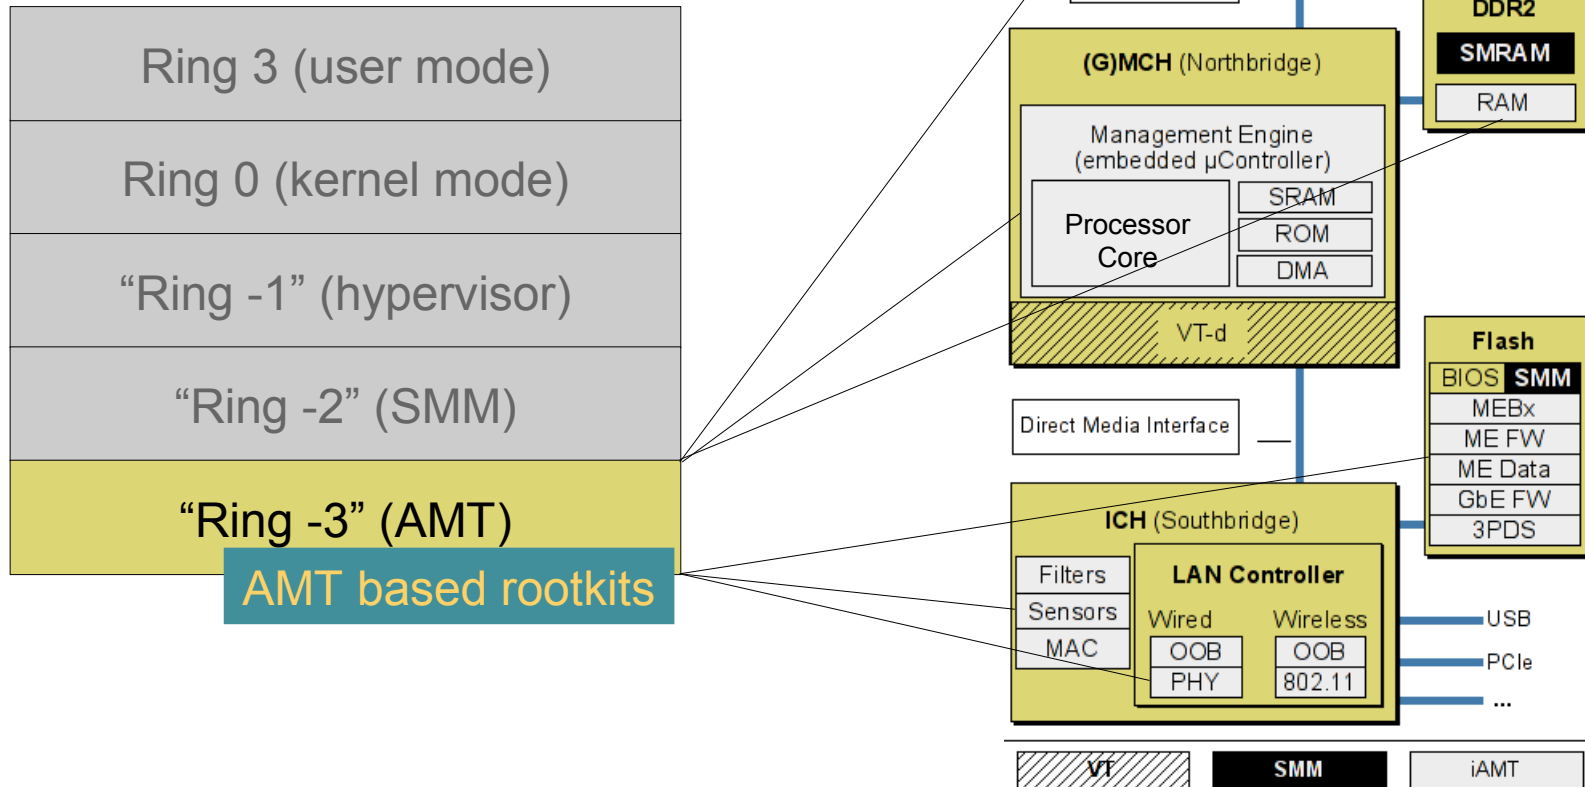

# Analysis of x86 Platform

- **System Management Mode (SMM):**  
Special Processor Mode

# Analysis of x86 Platform

- Intel Active Management Technology (iAMT):

# Challenges for Attackers/Rootkits

	Hardware	iAMT (Ring -3)	SMM (Ring -2)	Firmware	VMM (Ring -1)	Kernel-mode (Ring 0)	User-mode (Ring 3)
<b>Infiltration</b>							
Supply Chain						cooperation	
Update Service						router/ personal firewall	digital signature checks
E-mail/ Download						signature spoofing	digital signature checks
Security Vulnerability						exploitable until publicly known	
<b>Data Collection</b>							
Isolation			DeepWatch		DeepWatch	VM introspection	intrusion detection
					hardware discrepancies		antivirus
				kernel hook	Red Pill		behavior blocking
		FW measurement			Red Pill		integrity checks
Amount of Data						performance loss	
<b>Exfiltration</b>							
Outbound Channel/ Traffic				router firewall			router/ personal firewall
					hide channel/ traffic		

**Monitor is trustworthy**

**Could be used to attack monitor**

# Conclusion and Further Research

- Modern x86 platforms have very powerful stealth capabilities (stealthier than root in user mode)
  - Cf. kernel mode, VMBSR, SMM, iAMT
- Basis for monitor environment
  
- **Further Research:**
  - Countermeasures against rootkits (e.g., ring -3 rootkits)
  - Measurement strategy (cf. TOCTOU example)
    - When and what to measure?
      - Depends on use cases!
    - Which “ring”?
  - Develop runtime monitoring/attestation system according to measurement strategy

Questions?

Thank you!
