#### Abstract

Since the discovery of Buckminster fullerene C60 in 1985, carbon materials have been intensively studied. Carbon allotropes such as fullerenes, carbon nanotubes, diamonds, and graphite have been proven to have a splendid potential for applications in many kinds of devices such as quantum computers, organic solar cells, and transistors.

Among those carbon allotropes, fullerenes stand out by their uniform sizes which allow for precise structural control at the molecular level. In addition to the versatility in molecular engineering, the small size of fullerenes allows to study them inside a nanoscopic object, e.g. carbon nanotubes. Fullerenes under nano-confinement are known to show different physical and chemical properties such as chain-like polymer formation inside carbon nanotubes. In addition, research on assembled fullerenes is of great interest across a variety of fields. The assembly of fullerenes in various forms such as (liquid)crystals, films and solutions contributes to the development of materials with tunable properties.

Furthermore, incorporation of guests in between the assembled fullerenes endows the assembly with electronic perturbation. To name an example, fullerides are known to show superconductivity at relatively high temperature. Fullerides are crystals of a salt comprised of fullerene radical anions and alkali metals. The latter occupy the vacant sites in between the fullerene radical anions which are arranged in a face-centered cubic packing pattern. To gain comprehensive understanding of both nano-confinement effects and incorporation of guests in between C 60 S , coordination cages are one of the most appropriate host candidates. Coordination cages are synthesized via metal-mediated self-assembly of organic ligands. The properties of the inner cavities are often inherited from the properties of the organic ligands. Besides, some coordination cages can encapsulate multiple guest molecules. Owing to those features, coordination cages are well suited hosts for the investigation of fullerenes under nano-confinement as well as guest-incorporation in between well-aligned $\mathrm{C}_{60}$ assemblies. Therefore, this work has been focusing on the development of coordination cages designed for fullerene(s) $\mathrm{C}_{60}$ encapsulation and the investigation of the physical and chemical properties of the encapsulated fullerene(s) based on two keywords, nano-confinement and hierarchical assembly.

In this dissertation, the synthesis of triptycene-based organic ligands and the selfassembly of the ligands and Pd (II), as well as encapsulation of $\mathrm{C}_{60}$ molecule(s) inside

the resulting cages are shown. A cationic $\mathrm{Pd}_{2} \mathrm{~L}_{4}$ coordination cage can encapsulate $\mathrm{C}_{60}$ quantitatively inside the cavity surrounded by the triptycene backbone. The coordination cage was found to stabilize rather unstable $\mathrm{C}_{60}$ radical anion for a longer period (up to 1 month) inside its cavity.
Furthermore, the guest encapsulation scope of the $\mathrm{Pd}_{2} \mathrm{~L}_{4}$ coordination cage has been investigated. The coordination cage was found to encapsulate not only $\mathrm{C}_{60}$, but also two corannulene molecules and various $\mathrm{C}_{60}$ derivatives. The simple addition of $\mathrm{CS}_{2}$ was found to liberate the entrapped $\mathrm{C}_{60}$ derivative, $\mathrm{PC}_{61} \mathrm{BM}$, in a non-disruptive manner. A repetitive uptake and release of $\mathrm{PC}_{61} \mathrm{BM}$ using the coordination cage was demonstrated.
In addition to the host-guest capability, the $\mathrm{Pd}_{2} \mathrm{~L}_{4}$ coordination cage was found to act as a protecting group to synthesize $\left[\eta^{2}-\mathrm{C}_{60}(\operatorname{Pd}(0) L) n\right](n=1,2)$ complexes. In the confined environment, $\left[\eta^{2}-\mathrm{C}_{60}(\mathrm{Pd}(0) \mathrm{L})_{n}\right]$ is prevented from polymerization, inevitable in the free form. In order to stabilize the resulted unstable $\left[\eta^{2}-\mathrm{C}_{60}(\mathrm{Pd}(0) \mathrm{L}) n\right]$, an organic ligand based on thianthrene was synthesized. The thianthrene-based ligand was found to undergo cage-to-cage transformation from a $\mathrm{Pd}_{3} \mathrm{~L}_{6}$ ring to a $\mathrm{Pd}_{2} \mathrm{~L}_{4}$ cage upon encapsulation of $\mathrm{C}_{60}$.

Beside such $\mathrm{Pd}_{2} \mathrm{~L}_{4}$ coordination cage, a pill-shaped coordination cage capable of encapsulating two molecules of $\mathrm{C}_{60}$ within its cavities has been synthesized. The pillshaped coordination cage was synthesized by bridging two bowl-shaped coordination cages with two 2,6-naphthalene dicarboxylates. Owing to the good alignment of two C60s inside the coordination cage, investigations of the chemistry within a nanoscopic space surrounded by the outer surface of the encapsulated $\mathrm{C}_{60}$ s were performed. That nanoscopic space can accommodate a single corannulene molecule resulting in the formation of a charge-transfer complex between the entrapped $\mathrm{C}_{60}$ and corannulene. In addition, within the nanoscopic space, the Diels-Alder reaction between $\mathrm{C}_{60}$ and anthracene takes place quantitatively at a higher reaction rate compared to naked $\mathrm{C}_{60}$ and anthracene. Further, we elucidated the unique topochemical-like reaction inside the pill-shaped cage initiated by the Diels-Alder and retro Diels-Alder reactions with 9,10-dimethylanthracene and the encapsulated $\mathrm{C}_{60}$ s.
Up to now, a variety of coordination cages which can encapsulate fullerene(s) have been synthesized. Based on such well-established molecular designs and knowledges, the investigations of the encapsulated $\mathrm{C}_{60}(\mathrm{~s})$ could be conducted such as stabilization of $\mathrm{C}_{60^{\circ}}$, recycling encapsulation and release of $\mathrm{PC}_{61} \mathrm{BM}$, synthesis of $\left[\eta^{2}-\mathrm{C}_{60}(\mathrm{Pd}(0) \mathrm{L}) \mathrm{n}\right](\mathrm{n}=1,2)$ complexes, and host-guest chemistry in between the wellaligned $\mathrm{C}_{60}$ S.

## Zusammenfassung

Seit der Entdeckung von Buckminster-Fulleren $\mathrm{C}_{60}$ im Jahr 1985 werden Kohlenstoffmaterialien intensiv untersucht. Kohlenstoffallotrope wie Fullerene, Kohlenstoff-Nanoröhren, Diamant und Graphit haben sich für die Anwendung in vielen Arten von Geräten und elektronischen Bauteilen wie Quantencomputern, organischen Solarzellen und Transistoren als hervorragend geeignet erwiesen.
In der Familie der Kohlenstoff-Allotrope zeichnen sich die Fullerene durch ihre einheitliche Größe aus, die eine präzise Strukturkontrolle bei Reaktionen auf molekularer Ebene ermöglicht. Neben der Vielseitigkeit ihres Einsatzes in der Molekulartechnik kann wegen der geringen Größe der Fullerene auch ihr Verhalten innerhalb nanoskopischer Objekte, wie z. B. Kohlenstoff-Nanoröhren, untersucht werden.
Es ist bekannt, dass Fullerene im nano-begrenzten Raum unterschiedliche physikalische und chemische Eigenschaften aufweisen. Beispielsweise bilden sie innerhalb von Kohlenstoff-Nanoröhren kettenartige Polymere. Darüber hinaus ist die Forschung an assemblierten Fullerenen in unterschiedlichsten Bereichen von großem Interesse. Die Assemblierung von Fullerenen zu verschiedenartigen Systemen, wie (Flüssig-)Kristallen, Filmen und Lösungen, trägt zur Entwicklung von Geräten bei, die diese Eigenschaften der Fullerene nutzen.
Darüber hinaus können durch den Einbau von „Gästen" zwischen die assemblierten Fullerene die Eigenschaften dieser Assemblierungen moduliert werden. Beispielsweise sind die sog. Fulleride dafür bekannt, dass sie bei relativ hohen Temperaturen Supraleitfähigkeit zeigen. Fulleride sind Kristalle eines Salzes, das aus Fulleren-Radikalanionen und Alkalimetallen besteht. Letztere besetzen die freien Plätze zwischen den Fulleren-Radikalanionen, die in einem kubisch flächenzentrierten Gitter angeordnet sind.
Um ein umfassendes Verständnis sowohl für Effekte im nano-begrenzten Raum als auch für den Einbau von Gästen zwischen geordneten $\mathrm{C}_{60}$-Fullerenen zu erlangen, zählen Koordinationskäfige zu den sehr gut geeigneten Kandidaten für Wirt-Systeme. Koordinationskäfige werden durch die metallvermittelte Selbstassemblierung von organischen Liganden und Metallen synthetisiert. Die Eigenschaften der Kavitäten der Käfige entsprechen häufig denen der organischen Liganden. Einige Koordinationskäfige können auch mehrere Gastmoleküle aufnehmen. Aufgrund dieser Eigenschaften sind Koordinationskäfige sowohl für Untersuchungen von Fullerenen im nano-begrenzten Raum als auch hinsichtlich ihrer Assemblierung geeignet. Daher konzentriert sich diese Arbeit auf die Entwicklung von Koordinationskäfigen, die Fulleren(e) (C60) einlagern können und auf die Untersuchung der physikalischen und
chemischen Eigenschaften von eingelagertem/eingelagerten Fulleren(en) (C60), unter dem Blickwinkel „Nano-Begrenzung" und „Assemblierung".
In dieser Dissertation werden die Synthese von organischen Liganden auf Triptycenbasis, die Selbstassemblierung der Liganden mit $\mathrm{Pd}(\mathrm{II})$ sowie die Einkapselung von $\mathrm{C}_{60}$-Molekülen innerhalb der Kavitäten der resultierenden Käfige beschrieben. Es zeigte sich, dass ein kationischer Pd ${ }_{2} \mathrm{~L}_{4}-K o o r d i n a t i o n s k a ̈ f i g ~ d a s ~ e h e r ~$ instabile $\mathrm{C}_{60}$-Radikalanion über einen längeren Zeitraum (bis zu einem Monat) in seinem Hohlraum stabilisieren kann. Darüber hinaus wurde die Kapazität des Pd2L4Koordinationskäfigs bzgl. der Einlagerung von Gästen untersucht. Es konnte gezeigt werden, dass der Koordinationskäfig nicht nur $\mathrm{C}_{60}$ sondern auch zwei Corannulen Moleküle sowie diverse Fulleren-Derivate einlagert. Die Zugabe von $\mathrm{CS}_{2}$ führte zur Freisetzung des eingelagerten Fulleren-Derivats $\mathrm{PC}_{61} \mathrm{BM}$ unter Beibehaltung der Integrität des Käfigs. Es konnte gezeigt werden, dass die Aufnahme von PC61BM in den Käfig und seine Freisetzung wiederholbar sind.
Ferner wurde festgestellt, dass der Pd2L4-Koordinationskäfig als Schutzgruppe bei der Synthese von $\left[\eta^{2}-\mathrm{C}_{60}(\operatorname{Pd}(0) \mathrm{L}) \mathrm{n}\right](\mathrm{n}=1,2)$-Komplexen fungiert. Im begrenzten Raum wird dadurch die Polymerisation von $\eta^{2}-\mathrm{C}_{60} \mathrm{Pd}(0)$ n verhindert, die ohne die KäfigSchutzgruppe nicht zu vermeiden ist. Um das dabei gebildete $\eta 2-\mathrm{C}_{60} \mathrm{Pd}(0) \mathrm{n}$ zu stabilisieren, wurde ein organischer Ligand auf Thianthren-Basis synthetisiert. Bei Zugabe von $\mathrm{Pd}(\mathrm{II})$ bildet sich ein $\mathrm{Pd}_{3} \mathrm{~L}_{6}$ Ring, welcher bei Einlagerung von $\mathrm{C}_{60}$ infolge einer Käfig-zu-Käfig-Transformation in $\mathrm{Pd}_{2} \mathrm{~L}_{4}$ umgewandelt wird.
Neben den beschriebenen PdzL4 Koordinationskäfigen gelang die Synthese eines pillenförmigen Käfigs, der in der Lage ist, zwei $\mathrm{C}_{60}-$ Moleküle einzulagern. In diesem Käfig sind zwei schüsselförmige Koordinationskäfige durch zwei 2,6-Naphthalen-dicarboxylat-Linker-Einheiten verbunden. Dank der geeigneten Ausrichtung von zwei $\mathrm{C}_{60}$-Molekülen innerhalb des Koordinationskäfigs konnten Untersuchungen zur Chemie in einem nanoskopischen Raum, der von den Außenflächen der eingelagerten C60-Moleküle umgeben ist, durchgeführt werden. In diesem nanoskopischen Raum kann ein einzelnes Corannulen-Molekül binden, wobei sich ein Charge-TransferKomplex zwischen dem eingekapselten $\mathrm{C}_{60}$ und Corannulen bildet. Zusätzlich wurde gezeigt, dass im nanoskopischen Raum die Diels-Alder-Reaktion zwischen $\mathrm{C}_{60}$ und Anthracen quantitativ und mit höherer Reaktionsgeschwindigkeit abläuft als bei der Reaktion von freiem $\mathrm{C}_{60}$ mit Anthracen.
Bisher wurde bereits eine Vielzahl von Koordinationskäfigen synthetisiert, die Fullerene einlagern können. Die meisten Untersuchungen zu solchen Koordinationskäfigen konzentrierten sich jedoch nur auf das Phänomen der Einkapselung. Daher können die in dieser Arbeit gezeigten Forschungsergebnisse den Weg für die Untersuchung von Wirt-Gast-Komplexen mit Fullerenen ebnen, die über deren bloße Einlagerung hinausgehen.

## 1 General Introduction

### 1.1 The Era of Carbon

Carbon is one of the most prevalent elements in a variety of molecules. Modern society produces energy by burning fossil fuels comprised of (hydro)carbons. Meanwhile, as a result of the production of the energy, carbon atoms are transformed into carbon dioxide $\left(\mathrm{CO}_{2}\right)$ which causes global warming, the biggest issues mankind is facing. Carbon can generate $\mathrm{sp}, \mathrm{sp}^{2}$ and $\mathrm{sp}^{3}$ hybridized orbitals by forming covalent bonds. Owing to the diverse hybridization modes, carbon can form many different allotropes e.g. diamond, fullerene, carbon nanotube, and graphene (Figure 1.1.1). Carbon allotropes are studied for their potential use in a variety of devices in the future. From both aspects of global warming and the potential of carbon materials, the $21^{\text {st }}$ century may be named the era of carbon.
(a)

(c)

Figure 1.1.1 Structures of representative allotropes of carbon (a) diamond (b) fullerene $\mathrm{C}_{60}$ (c) carbon nanotube and (d) graphene

Because of the peculiar abilities such as electrical and thermal conductivities, carbon allotropes have become an appealing field of research for both synthetic and material chemists. ${ }^{[1,2]}$ The intense research about carbon materials has begun since the discovery of Buckminster-fullerene $\mathrm{C}_{60 .}{ }^{[3]}$ Fullerenes and their derivatives show electron accepting and transporting abilities which have been exploited in organic photovoltaics. ${ }^{[4,5]}$ Stimulated by the discovery of $\mathrm{C}_{60}$, carbon nanotubes were later discovered by an arc-discharge evaporation method in 1991. ${ }^{[6]}$ The carbonaceous tubes are light yet extremely strong materials. ${ }^{[7,8]}$ In 2004, single graphite layers, so called graphene, were prepared and the physical properties have been extensively investigated since then. ${ }^{[9]}$ Graphene is known for its ambipolar field effect, quantum Hall effect and so forth. ${ }^{[10]}$ As strongly represented by the attribution of the Nobel prizes
in 1996 and 2010 for the discoveries of fullerene $\mathrm{C}_{60}$ and graphene, respectively, countless attention has been paid to those novel materials consisting of carbon atoms only. In fact, new synthetic carbon materials have been continuously reported. ${ }^{[11]}$

### 1.2 Fullerenes

Figure 1.2.1 (a) Variety of examples of functionalization of $\mathrm{C}_{60}$, (b) Structure of bulk heterojunction organic solar cell devices ${ }^{[12]}$ with $\mathrm{PC}_{61} \mathrm{BM}$ as an electron accepting material, (c) Structures of endohedral-fullerene $\mathrm{C}_{60}$ encapsulating $\mathrm{H}_{2}{ }^{[13]}$ and $\mathrm{H}_{2} \mathrm{O}^{[14]}$, (d) Structure of $\mathrm{C}_{60}$ derivative utilized for gene delivery ${ }^{[15]}$

One of the biggest differences of fullerenes from the other carbon allotropes is the facileness of its molecular engineering. Unlike other carbon materials such as carbon nanotubes or graphene, fullerenes can be obtained in a uniform size and structure. ${ }^{[16]}$ In addition, fullerenes can be solubilized in organic solvents in contrast to graphene or carbon nanotubes. While control of the length and the diameter of carbon nanotubes is hard, separation methods for many different fullerenes have been already reported. ${ }^{[17]}$ Among fullerenes, $\mathrm{C}_{60}$ is the most abundant, and thus, best studied fullerenes so far. $\mathrm{C}_{60}$ can be handled as a single molecule which is beneficial for a better understanding of its physical and chemical properties. Furthermore, many chemical modifications of $\mathrm{C}_{60}$ have been reported so far which opened the access to functionalized $\mathrm{C}_{60}$ derivatives (Figure 1.2.1a). ${ }^{[18-20]}$ Owing to the development of
functionalization of $\mathrm{C}_{60}$, applications of $\mathrm{C}_{60}$ derivatives varied into photovoltaics, ${ }^{[4,12,21]}$ single molecular storage, ${ }^{[13,14]}$ and even biomedicine (Figure 1.2.1b-d). ${ }^{[22]}$ Beside the aspect of molecular engineering, $\mathrm{C}_{60}$ presents an ideal size to be investigated under confinement contrary to carbon nanotubes or graphene. Upon the establishment of the mass production of $\mathrm{C}_{60}$ by Krätschmer and Hoffman ${ }^{[23]}$, encapsulation of $\mathrm{C}_{60}$ inside a variety of hosts have been investigated.

(b)

(c)

Figure 1.2.2 (a) 3:1 complex of hydroquinones and $\mathrm{C}_{60}$ (b) host-guest complex of $\mathrm{C}_{60}$ and $\gamma$-cyclodextrin and (c) illustration of carbon nano-peapod ${ }^{[24]}$

The first example of $\mathrm{C}_{60}$ adsorption inside a host was reported by Ermer et al.. ${ }^{[25]}$ Ermer co-crystalized hydroquinone and $\mathrm{C}_{60}$ to obtain such a host-guest complex in which $\mathrm{C}_{60}$ sits in a space surrounded by six hydroquinones connected via a hydrogen-bonding network (Figure 1.2.2a). A subsequent example of encapsulation of $\mathrm{C}_{60}$ was reported in 1992 by Wennerström. ${ }^{[26]}$ Wennerström utilized $\gamma$-cyclodextrin to capture $\mathrm{C}_{60}$ into the hydrophobic cavity of the host (Figure 1.2.2b). Among many reports on encapsulation of $\mathrm{C}_{60}$, one of the biggest achievements was the observation of a carbon peapod, a molecular composite of $\mathrm{C}_{60}$ and single walled carbon nanotube, reported by Luzzi and Smith (Figure 1.2.2c). ${ }^{[24]}$ In the structure of the carbon peapod, $\mathrm{C}_{60}$ S are filling the hollow cavity of the carbon nanotube. Carbon peapods can be considered as a new class of carbon material as some of them display different physical properties from both the carbon nanotube and $\mathrm{C}_{60}$. In addition, some reports have shown that trapped C 60 s inside a carbon nanotube display different physical and chemical properties. ${ }^{[27]}$ For instance, a linear chain of $\mathrm{C}_{60}$ S connected via covalent bonds displaying metallic characters have been reported by Achiba and co-workers. ${ }^{[28]}$ The $\mathrm{C}_{60}$-chain can be synthesized by doping potassium to nano-peapods and exists only in the carbon nanotube. Note, that the topology of the $\mathrm{C}_{60}$-chains should be defined by the inner environment of the carbon nanotube. Such control of the topology would
have been difficult without the template effect by the carbon nanotube owing to the spherical structure of $\mathrm{C}_{60}$ with the same reactivity of all the bonds. ${ }^{[29]}$ As can be seen in those examples, $\mathrm{C}_{60}$ under nano-confinement is an intriguing object to be investigated.

Figure 1.2.3 $\mathrm{C}_{60}$ arrays in solid-state, solution-state, and inside host

In addition, aligned $\mathrm{C}_{60}$ s are of great interest as well. Due to the electron accepting and transporting abilities of $\mathrm{C}_{60}$, assemblies of $\mathrm{C}_{60}$ have gained attentions to develop various functional arrays. ${ }^{[30-32]}$ For instance, an embedded manner of $\mathrm{C}_{60} / \mathrm{C}_{60}$ derivatives plays a crucial role to achieve higher electron mobility and efficiency in electronic devices. ${ }^{[33,34]}$ A key feature resulting from such a morphological control of fullerenes is to manipulate weak interactions. Self-assembled pristine $\mathrm{C}_{60}$ and its derivatives have been investigated in various forms such as (liquid)crystals, films, fibres and so forth. ${ }^{[30-32]}$ Introduction of chemical pendants on $\mathrm{C}_{60}$ is often required to realize such assemblies due to scarce interactions between pristine $\mathrm{C}_{60}$. Thus, investigations of intact $\mathrm{C}_{60}$ S in an ordered-form have been done mostly in the solid state. ${ }^{[35]}$ Pristine $\mathrm{C}_{60}$ is known to crystalize into face-centered-cubic Bravais lattice (Figure 1.2.3). ${ }^{[36]}$ When $\mathrm{C}_{60}$ is treated with an alkali metal, a material showing superconductivity can be obtained. The resulting material in the crystalline state is called fulleride. Fullerides can be regarded as salts composed of $\mathrm{C}_{60}$ anions and alkali metal cations as a result of electron transfer from the doped alkali metals to $\mathrm{C}_{60}$. In the solid-state structure of fullerides, alkali metal cations occupy the vacant sites of $\mathrm{C}_{60}$ crystals in the cubic crystal system. ${ }^{[37]}$ Furthermore, some fullerides are superconductive at a relatively high temperature. ${ }^{[38]}$ Thus, fullerides shed light on the potential of incorporation of guests in between aligned $\mathrm{C}_{60 \text { s }}$ for material development. Spurred by these properties, examples of incorporation of guest molecules, such as
haloform, ethylene, carbon disulphide and so on, within assembled $\mathrm{C}_{60}$ s have been reported. ${ }^{[39-46]}$ However, such investigation is, again, limited in the solid-state in most of the cases. Assembling $\mathrm{C}_{60}$ in solution has been hampered by the scarce interactions between $\mathrm{C}_{60}$. One possibility to deploy $\mathrm{C}_{60}$ s in a precise arrangement in solution could be the utilization of host molecules like molecular peapods (Figure 1.2.3). Therefore, it is an intriguing topic to synthesize a host enabling to conduct research on guest incorporation in between C60-assembly in solution. Amongst host molecules enabling investigations of $\mathrm{C}_{60}$ (s) both under "nano-confinement" and "assembly", coordination cages are one of the most suitable candidates.

### 1.3 Coordination Cages

Figure 1.3.1 (a) concept of metal-mediated self-assembly (b) Synthesis of doublestranded helicate templated by $\mathrm{Cu}(\mathrm{I})^{[47]}$ (c) Synthesis of square-shaped coordination ring ${ }^{[48]}$

Coordination rings and cages are a compound class having discrete structures formed via metal-mediated self-assembly of organic ligands and metals (Figure 1.3.1a). JeanMarie Lehn first demonstrated the power and the versatility of metal-mediated selfassembly by the synthesis of double stranded helicates (Figure 1.3.1b). ${ }^{[47]}$ Two of oligo-bipyridine ligands form the double stranded helicates hinged by $\mathrm{Cu}(\mathrm{I})$ metals. As can be seen in the example, by mixing organic ligands and metals, if necessary under heating, a precise discrete structure is assembled as the thermodynamic species. Based on this concept, Fujita and co-workers reported the quantitative synthesis of a square-shaped coordination complex by self-assembly of 4,4'-bipyridins and cisprotected $\mathrm{Pd}(\mathrm{II})$ (Figure 1.3.1c). ${ }^{[88]}$ The utilization of the metals as the nodes of the structure introduces angles which cannot be provided by bonds of organic elements. In fact, numerous topologies can be created in coordination cages. ${ }^{[49]}$ Depending on the bite-angle and the coordination geometry of the metal, structure of coordination cages can be quite diversified compared with organic cages. The various topologies in coordination cages broadens the utility of these assemblies in several fields. One of the most important structural features of coordination cages is their cavities inside. ${ }^{[50]}$

Supramolecular chemistry has been flourished since the synthesis of crown ethers and their encapsulation capability toward alkali metal ions were showcased by Pederson. ${ }^{[51]}$ Molecular recognition and encapsulation as well as subsequent hostguest chemistry is a center of the supramolecular chemistry field. Coordination cages can be used to encapsulate various molecules within their cavities. Coordination cages are often charged owing to the metal nodes and thus possess a hydrophilic outer shell while their inner space is hydrophobic, which allows encapsulation of hydrophobic organic molecules. The inner cavities can store reactive species, ${ }^{[52,53]}$ catalyze reactions, ${ }^{[54]}$ recognize subtle structural difference ${ }^{[55-57]}$ and so forth. ${ }^{[58-60]}$ Furthermore, the size and number of cavities can be finely controlled by a proper choice of organic ligands. ${ }^{[61]}$

In the Clever group, where this doctoral research was conducted, coordination cages comprised of banana-shaped organic ligands and $\mathrm{Pd}(\mathrm{II})$ have been intensively studied (Figure 1.3.2). ${ }^{[59,62-64]}$ One of the greatest achievements of the group is a systematic study of self-assembly of such coordination cages bringing multiple organic ligands and $\mathrm{Pd}(\mathrm{II})$ together. In the course of the exploration, the group has suggested and demonstrated a concept of rational syntheses of heteroleptic coordination cages in which more than two different organic ligands are joined to form the structures. For synthesizing heteroleptic coordination cages, contributions of both entropy and enthalpy must be considered to achieve a stable assembly. The strategies the Clever group has suggested are namely "Shape Complementarity Assembly" (SCA) and "Coordination Sphere Engineering" (CSE). In the first concept, our group has demonstrated the synthesis of heteroleptic coordination cages by bringing two different organic ligands having different bite angles together (Figure 1.3.2b). The different bite angles complement each other so that Pd(II) can adopt a square planar coordination geometry, which helps coordination cages to have less strain energy. ${ }^{[65,66]}$ In the latter concept, the introduction of steric bulk directly around the coordination sites can control the topology of resulting coordination cages (Figure 1.3.2c). ${ }^{[64,67,68]}$ For example, organic ligands 4 and 5 having pycolyl coordination-sites yield heteroleptic coordination cage $\mathrm{Pd}_{2} \mathbf{4}_{2} 5_{2}$ by self-assembly with $\mathrm{Pd}(I I)$. The steric bulk around the coordination-sites disfavors narcissistic self-sorting. Based on the concepts explained above, various coordination cages showing unique physical properties have been reported by the group. ${ }^{[59,62-64]}$ The synthesized cationic coordination cages enable encapsulation of anionic guests within the cavities.[69]

However, examples of encapsulation of neutral guest molecules are still quite limited. ${ }^{[70]}$ For encapsulation of neutral guest molecules, a well-isolated space surrounded by motifs which allow multiple weak interactions with the guest is required to overcome solvation effects. In light of this, organic ligand 6 has been synthesized and its behavior in the self-assembly with $\mathrm{Pd}(\mathrm{II})$ has been investigated (Figure 1.3.3). ${ }^{[71]} 6$ has a structural resemblance to triptycene which is known for convexconcave interactions with fullerene. ${ }^{[72]}$

Figure 1.3.2 X-ray structure of a $\mathrm{Pd}_{2} 1_{4}$ coordination cage ${ }^{[69]}$, (b) X-ray structure of a heteroleptic coordination cage $\mathrm{Pd}_{2} \mathbf{2}_{2} \mathbf{3}_{2}{ }^{[66]}$, where the hexyl chains are omitted for clarity, and (b) model structure of $\mathrm{Pd}_{2} \mathbf{4}_{2} \mathbf{5}_{2}$. ${ }^{[67]}$ In the X-ray structures, solvent molecules, counter anions, disorders are omitted for clarity unless otherwise stated.
(a)

(b)

Figure 1.3.3 (a) Secondary structure of $\mathrm{C}_{60}$ and triptycene in the solid state ${ }^{[72]}$, (b) syntheses of $\mathrm{C}_{60} @ \mathrm{Pd}_{2} 6_{4}, \mathrm{C}_{60} @ \mathrm{Pd}_{2} 7_{3}(\mathrm{MeCN})_{2}$, and $\mathrm{CC}_{60} @ \mathrm{Pd}_{4} 7_{6}(\mathrm{TPA})_{2}$
$\operatorname{Pd}(I I)$-mediated self-assembly of 6 brings four of the ligands together to create a nanoscopic space which is suitable for the encapsulation of a single fullerene $\mathrm{C}_{60}$ inside. In addition, self-assembly of 7 and $\mathrm{Pd}(I I)$ leads to the formation of coordination bowl $\mathrm{Pd}_{2} 7_{3}(\mathrm{MeCN})_{2}$. The coordination bowl can also encapsulate $\mathrm{C}_{60}$ as well as $\mathrm{C}_{70}$ within the cavity. Instead of the fourth ligand, two acetonitrile molecules are coordinated to the $\mathrm{Pd}(\mathrm{II})$ centers. The weakly bound acetonitrile molecules can be replaced by anionic carboxylate linkers, such as terephthalate (TPA), yielding a pillshaped coordination cage. The elongated cavities of the pill-shaped coordination cage can be filled with two fullerenes $\mathrm{C}_{60}$ or $\mathrm{C}_{70}$. These examples show the potential of coordination cages as a platform for investigating nano-confinement effects and assembly of more than two C6os. Note that, coordination cages are soluble in polar organic solvents thanks to their charges making the investigations in the solution-state possible.

To point out what has been achieved and what is next in this research field, host molecules including coordination cages for $\mathrm{C}_{60}$ encapsulation, will be described in the next section.

### 1.4 Encapsulation of Fullerene

Figure 1.4.1 Comparison of weak binding and strong binding of $\mathrm{C}_{60}$ encapsulation

### 1.4.1 The dawn of fullerene-binders

At the dawn of fullerene-binders, a few numbers of compounds were mainly applied to capture fullerene $\mathrm{C}_{60}$ or $\mathrm{C}_{70}$. The first host-guest complex accommodating $\mathrm{C}_{60}$ was reported by Ermer in 1991 (Figure 1.2.2a). ${ }^{[25]}$ Intermolecular hydrogen-bonding networks bring hydroquinones to form a clathrate with $\mathrm{C}_{60}$ and also $\mathrm{C}_{70}$. The nanoscopic space surrounded by six hydroquinones accommodates $\mathrm{C}_{60} / \mathrm{C}_{70}$ via $\pi-\pi$ interactions. A subsequent example of fullerene encapsulation was reported in 1992 by Wennerström and co-workers. They employed $\gamma$-cyclodextrin to capture and solubilize $\mathrm{C}_{60}$ in water (Figure 1.2.2b). ${ }^{[26]}$ This result implied that the solubility of $\mathrm{C}_{60}$ is inherited from the host. From these two reports, two implicit criteria to encapsulate fullerene can be extracted. First, hosts should be composed of a moiety which allows weak interactions, i.e. $\pi-\pi$ interactions, with the surface of fullerene. Second, hostmolecules should be able to provide a nanoscopic space to the globular shape of fullerene. Calix[n]arenes are ideal molecules fulfilling the prerequisites as they are composed of a certain number of phenol molecules and their concave structure fits the convex fullerene-surface. In fact, a number of fullerene-binders based on calix[n]arenes have been reported. ${ }^{[73]}$ In 1994, the groups of Atwood and Shinkai simultaneously discovered that para-tert-butyl-[8]-calixarene can selectively bind $\mathrm{C}_{60}$ in $1: 1$ ratio, which is beneficial for a facile $\mathrm{C}_{60}$ purification. ${ }^{[74,75]}$ Since calix[n]arenes present diverse and dynamic structural features depending on the number of phenols
contributing to form the macrocycle, encapsulation behavior widely varies especially in the solid state. ${ }^{[35]}$ For instance, a calix[5]arene derivative prefers to form a 2:1 complex with fullerene $\mathrm{C}_{60}$ in the solid state, while a $1: 1$ complex is formed in the solution state. ${ }^{[76]}$

Two of the most famous substructures of fullerenes are namely corannulene ${ }^{[77]}$ and sumanene. ${ }^{[78]}$ In 1993, Bohne and co-workers showcased a reaction between corannulene and $\mathrm{C}_{60}$ in the gas phase. ${ }^{[79]} \mathrm{An}$ adduct ion of $\mathrm{C}_{60}$ and corannulene is formed by reacting either corannulene radical cation with $\mathrm{C}_{60}$ or $\mathrm{C}_{60}$ radical cation with corannulene molecule. A pristine corannulene molecule does not have enough binding ability to form a molecular complex with $\mathrm{C}_{60}$ in the solution state most likely because of its $\pi$-surface. ${ }^{[80]}$ Cyclotriveratrylene is another bowl-shaped molecule which is able to form a host-guest complex with $\mathrm{C}_{60}$ in the solid state, firstly reported by Atwood and Raston. ${ }^{[81]}$ Not only bowl- or cup-shaped molecules but also saddle-shaped molecules can form a molecular complex with fullerenes $\mathrm{C}_{60}$ and $\mathrm{C}_{70}$ in the solid state. A nickel macrocycle 5,7,12,14-tetramethyldibenzo[b,i]1,4,8,11]tetraazacyclotetradecinenickel(II), having two concave surfaces, is a versatile host for formation of supramolecular arrays in the solid state with fullerene. ${ }^{[82]}$ Derivatives of the $\mathrm{Ni}(\mathrm{II})$ macrocycle assemble into various supramolecular arrays with C60 in several packing modes. ${ }^{[35]}$

Porphyrin is a flat molecule, however, the electron-rich aromatic molecule is often good at fetching fullerenes thanks to their good electron accepting ability. ${ }^{[83-85]}$ One of the earliest pioneering works of molecular complexes between $\mathrm{C}_{60}$ and a metalloporphyrin derivative, Cr (II)tetraphenylporphyrin ( Cr (II)TPP), was prepared in both solid and solution states by Wudl, Reed and co-workers. ${ }^{[86]} \mathrm{C}_{60}$ is reduced to $\mathrm{C}_{60}{ }^{-0}$ upon complexation. Combinations of fullerene and porphyrin derivatives are widely utilized in, for example, crystal-engineering, ${ }^{[87,88]}$ supramolecular chemistry, ${ }^{[85]}$ and artificial photosynthesis. ${ }^{[89,90]}$ Co-crystallization of fullerene and a porphyrin derivative often simplifies crystallographic analyses of fullerenes. ${ }^{[14,91]}$ In 1999, Feringa and coworkers showcased encapsulation of $\mathrm{C}_{60}$ inside a nano-space furnished in between triptycenes. ${ }^{[72]}$ The triangular molecule, triptycene, with three concave surfaces, cocrystalizes with $\mathrm{C}_{60}$ by sandwiching from two opposite sides. Introducing an N atom into triptycene substituting one of the $\mathrm{sp}^{3}$ carbons leads to a different crystal packing due to the electronic perturbation.

### 1.4.2 Strategy for fullerene encapsulation in organic solvents

Due to the weak binding ability of the host-molecules with fullerenes aforementioned, encapsulation of fullerene was largely limited either to the crystalline state or to aqueous media as hydrophobic fullerenes prefer to be isolated within a hydrophobic inner cavity of the host in aqueous media through the hydrophobic effect (Figure 1.4.1). The weak binding constants had been hindering further investigations of encapsulation of fullerenes in organic solvents. To strongly encapsulate fullerene not only in the solid state or in aqueous media but also in organic solvents, manipulation of weak-interactions, i.e. $\pi-\pi$ interactions and $\mathrm{C}-\mathrm{H} \cdot \bullet_{\mathrm{o}}$ interactions, is one of the most important factors. ${ }^{[92,93]}$ Fullerene-binders have evolved based on the promising backbones shown in the previous section to obtain a higher binding constant in organic solvents at the early stage. In this section, how fullerene-binders have been improved in terms of binding-constant in the last decades will be described. Fullerene-binders based on calix[n]arenes, buckybowls, porphyrins and carbon-nanohoops will be mainly depicted here.

Fukazawa and co-workers discovered that calix[5]arene derivative 8 strongly binds $\mathrm{C}_{60}$ in several organic solvents such as toluene, $\mathrm{CS}_{2}$, benzene, and o-dichlorobenzene with binding constant being $2.12 \times 10^{3} \mathrm{M}^{-1}$ in a toluene solution (Figure 1.4.2a). ${ }^{[76]}$ This study also showed that the binding constant decreased inversely against solubility of $\mathrm{C}_{60}$ in the organic solvents (cf. $K_{a}=3.08 \pm 0.41 \times 10^{2} \mathrm{M}^{-1}$ in o-dichlorobenzene, 2.12 $\pm 0.11 \times 10^{3} \mathrm{M}^{-1}$ in toluene). This indicates that solvation and binding of $\mathrm{C}_{60}$ are in competition. Therefore, to cover the surface of fullerene is important to realize a stronger binding of fullerene within a host in order to maximize the contacted surface between fullerene and the host alongside decreasing the contact to solvent molecules. Fukazawa and co-workers synthesized bridged bis-calix[5]arenes 9-11 and investigated the binding behavior of the hosts toward $\mathrm{C}_{60}$ and $\mathrm{C}_{70}$ in organic solvents. ${ }^{[94]}$ In fact, 9 encapsulates single $\mathrm{C}_{60}$ with a ca. 30 times larger binding constant, $K_{a}=76 \pm 5 \times 10^{3} \mathrm{M}^{-1}$, in toluene than 8. 9 can encapsulate also larger fullerene $\mathrm{C}_{70}$ with a higher binding constant, $K_{a}=163 \pm 16 \times 10^{3} \mathrm{M}^{-1}$, compared to the $K_{a}$ toward $\mathrm{C}_{60}$ in toluene. The tight encapsulation prevents $\mathrm{C}_{60}$ from being solvated.

(c)

(e)

Figure 1.4.2 Structure of covalently bonded fullerene-binders (a) 8-11 (b) 12-14 (c) 15 and X -ray structure of $\mathrm{C}_{60} @ 15$ and (d) 16 and $\mathrm{C}_{60} @ 16$ with disorder of $\mathrm{C}_{60}$

As mentioned in the previous section, a simple corannulene molecule shows only neglectable association with a neutral fullerene in the solution state. However, similar to calix[n]arenes, either to bridge two buckybowls or to expand the contacting surface with fullerene enhances the binding-ability and to form a host-guest complex with fullerene (Figure 1.4.2b). Scott and co-workers synthesized corannulene derivatives 12-14 by nucleophilic aromatic substitution reactions of a chlorinated corannulene derivative with the corresponding thiolates. ${ }^{[95]}$ The aromatic chemical pendants attached on the edge of corannulene endow 12-14 to form a 1:1 molecular complex with C60. Isobe and co-workers have reported gigantic buckybowl 15 (Figure 1.4.2c). ${ }^{[96]} 15$ can be regarded as a molecule in which all the carbon atoms of corannulene are replaced by benzene rings. The large surface of 15 covers almost half of the sphere of $\mathrm{C}_{60}$ and a $1: 1$ molecular complex is formed in benzene with a binding-constant of $3.4 \pm 0.1 \times 10^{4} \mathrm{M}^{-1}$. ${ }^{[97]}$

Nowadays, hosts which are composed of bridged aromatic compounds, so called molecular tweezers, are of great interest for the sake of fullerene-binding and their structural uniqueness. Molecular tweezers serve a well-defined nanoscopic space which is suitable to capture fullerenes. Sygula and co-workers reported first molecular tweezer 16 composed of two corannulene molecules in 2007 (Figure 1.4.2d). ${ }^{[98]} 16$ forms a molecular complex with $\mathrm{C}_{60}$ in 1:1 ratio in the crystalline state as well as the solution state. The NMR titration experiment revealed that molecular tweezer 16 binds $\mathrm{C}_{60}$ with $K_{a}=8.6 \pm 0.5 \times 10^{3} \mathrm{M}^{-1}$. Regarding porphyrin-based fullerene-binders, despite the preferable donor-acceptor relations between porphyrin and fullerenes, the planar structure is a disadvantage to prevent fullerene from solvation. Thus, the bridging strategy has been applied to porphyrins as well to increase binding ability toward fullerene. Covalently-bridged porphyrins 17 and 18 have been reported by Aida and co-workers (Figure 1.4.3a). ${ }^{[99]}$ Bridged-porphyrin dimer 17, in which two porphyrins located in a face-to-face manner, encapsulates one molecule of fullerene $\mathrm{C}_{60}$ in between the two panels in a benzene solution with a $K_{a}$ value being $6.7 \times 10^{5} \mathrm{M}^{-1}$. The solid-state structure of 19 encapsulating $\mathrm{C}_{60}$, in which the hexyl chains and the methyl groups on the porphyrins of 17 are replaced with ethyl groups, was elucidated by single crystal X-ray structure analysis two years later. ${ }^{[100]}$

Figure 1.4.4 Structure of macrocyclic fullerene-binders (a) 23 and [10]CPP (b) 24 and X-ray structure of $\mathrm{C}_{60} @ 24$ (c) 25 and X-ray structure of $\mathrm{C}_{60} @ 25$

Lang, Lhoték and co-workers have synthesized calix[4]arene-based molecular tweezer $\mathbf{2 0}$ and demonstrated that $\mathbf{2 0}$ captures fullerene $\mathrm{C}_{70}$ as well as $\mathrm{C}_{60}$ in between the two porphyrin panels (Figure 1.4.3b). ${ }^{[101]} \mathrm{A} 1: 1 \mathrm{C}_{70}$-inclusion molecular complex is formed by mixing $\mathrm{C}_{70}$ and 20 in toluene, and an association constant $K_{a}$ was determined to be $1.45 \times 10^{4} \mathrm{M}^{-1}$ by ${ }^{1} \mathrm{H}$ NMR titration. 20 displays preferable encapsulation towards $\mathrm{C}_{70}$ rather than $\mathrm{C}_{60}$. In addition to these porphyrin-based hosts, tubular macrocycles composed of metalloporphyrins also display a good binding ability toward $\mathrm{C}_{60}$. Osuka and co-workers synthesized 21 (Figure 1.4.3c). With an inner diameter of about $14 \AA, \mathbf{2 1}$ binds $\mathrm{C}_{60}$ within the tubular structure with an association constant of $5.3 \pm 0.1 \times 10^{5} \mathrm{M}^{-1} .{ }^{[102]}$ Recently von Delius and co-workers reported highly strained tubular porphyrin-macrocycle 22 showing a103-fold higher association constant for $\mathrm{C}_{60}$ than 21. The encapsulated $\mathrm{C}_{60}$ is located off-center of the tube (Figure 1.4.3d). ${ }^{[103]}$

Molecular complexes of carbon allotropes such as molecular peapods have been attracting attention due to their physical properties. ${ }^{[104]}$ For systematic understanding into hidden properties of such carbon composites, investigation at the molecular level is important. In this context, Kawase, Oda and co-workers investigated $\mathrm{C}_{60}$ encapsulation into [6]-cycloparaphenyleneacetylene 23 (Figure 1.4.4a). ${ }^{[105]}$ The association constant between 23 and $\mathrm{C}_{60}$ was estimated to be $1.6 \pm 0.3 \times 10^{4} \mathrm{M}^{-1}$ in
benzene. ${ }^{[106]}$ A substructure of CNTs, [n]cycloparaphenylenes ([n]CPPs), was independently synthesized by the groups of Bertozzi, ${ }^{[107]}$ Itami, ${ }^{[108]}$ and Yamago ${ }^{[109]}$ through different approaches. [ $n$ ]CPPs can be seen as a molecular model to investigate molecular peapods. Yamago and co-workers found that $\mathrm{C}_{60}$ can be selectively encapsulated in [10]CPP out of other [n]CPPs due to size-matching. The association constant was determined to be $2.79 \pm 0.03 \times 10^{6} \mathrm{M}^{-1}$ by fluorescence spectroscopy. ${ }^{[110]}$ The highest binding constant toward $\mathrm{C}_{60}$ so far was achieved by Isobe and co-workers. ${ }^{[111,112]}$ Macrocyclic hydrocarbon 24 encapsulates $\mathrm{C}_{60}$ with the highest association constant in the order of $10^{12}$ in benzene(Figure 1.4.4b). The binding-constant increases as the solubility of $\mathrm{C}_{60}$ becomes lower similar to most of other fullerene-binders. Solid-state dynamics of $\mathrm{C} 60 @ 24$ and its enantiomer have been also investigated. ${ }^{[113,114]}$ These researches show that host-guest complexes encapsulating fullerene are not merely of aesthetic appeal but that they can be a platform to investigate solid-state physics of fullerenes for instance. Macrocyclic hydrocarbons can encapsulate fullerene not only through $\pi-\pi$ interactions but also $\mathrm{CH}-\pi$ interactions. Toyota and co-workers reported macrocyclic host $\mathbf{2 5}$ composed of anthracenes (Figure 1.4.4c). The hydrogens pointing inward interact with the $\pi-$ surface of $\mathrm{C}_{60} / \mathrm{C}_{70}$ and thus 25 entraps fullerene within the macrocycle to form the Saturn-shaped host-guest complex. ${ }^{[115,116]}$

### 1.4.3 Fullerene-binders based on coordination cages

### 1.4.3.1 Designs and syntheses

26
27

$$
\mathrm{R}=-\left(\mathrm{OC}_{2} \mathrm{H}_{4} \mathrm{OCH}_{3}\right)
$$

Figure 1.4.5 Structure of coordination cages (a) 26-28 and X-ray structures of 26 and 28 (b) 29-C60@32 and X-ray structure of 29, 30, and $\mathrm{C}_{60} @ 32$. A modelled structure is shown for 31.

In the previous section, the history of fullerene-binders based on covalently-bonded host-molecules was briefly covered. To strongly bind fullerenes, host-molecules must be able to interact with the globular surface. As organic syntheses have been advancing over the decades, many covalently-bonded hosts designed for encapsulation of fullerene have been synthesized. The host-molecules have been extended, bridged, or hooped to provide a well-defined and isolated space to accommodate fullerene even in organic solvents. Hence, the synthetic routes tend to become more complicated and time-consuming. On the other hand, it has become easier to construct an isolated space to store unstable compounds, ${ }^{[52,53]}$ to create a reaction field, ${ }^{[50]}$ separate molecules by their structures ${ }^{[55,56]}$ thanks to metal-mediated
(a)

(b)

Figure 1.4.6 Schematic structure of (a) 29, 33-40 and (b) model structure of 41 and 42 without coronene pendants
self-assembly. In addition, a rational choice of organic ligands and metal centers makes it possible to assemble supramolecular complexes with a larger variety of topologies without laborious syntheses. ${ }^{[177,118]}$ Recently, a number of coordination cages designed for fullerene encapsulation have been reported. Covalently-bonded fullerene-binders are a good model to learn how to design organic ligands to capture fullerene. Following these experiences, the organic ligands should be based on a moiety which offers weak-interactions with globular fullerene. In addition, the assembled cages must possess a well-defined nanoscopic space for fullerene. Flat aromatic compounds are attractive molecules for this sake because their $\pi$-extended panels can induce favorable interactions with fullerene. Further, aromatic compounds are prone to halogenation reaction which is ideal for following with coupling reactions to attach coordination-sites. For example, Yoshizawa and co-workers reported Pd2L4 cage 26 whose inner space is surrounded by eight anthracene panels (Figure 1.4.5a). ${ }^{[119]}$ Sheer anthracene molecule does not have ability of accommodating other molecules, however, self-assembly brings anthracenes together and constructs the isolated space which shows outstanding encapsulation capability for a variety of guestmolecules in aqueous media. ${ }^{[120]} \mathbf{2 6}$ can encapsulate $\mathrm{C}_{60}$ quantitatively via multiple weak interactions. It is important to note that the encapsulation of C6o in $\mathbf{2 6}$ was performed heterogeneously. Yoshizawa and co-workers have also reported confinement of $\mathrm{C}_{60}$ in tubular coordination cage 27. ${ }^{[121]}$ The coordination numbers of the metal center is a decisive factor to determine the topology of coordination cages. In this study, $\mathrm{Ag}(\mathrm{I})$ was used as metal centers in lieu of $\mathrm{Pd}(\mathrm{II})$. Two pyridine coordination-sites of the ligand coordinate to $\mathrm{Ag}(\mathrm{I})$ center in a linear fashion and
tubular $\mathbf{2 7}$ is assembled. Although 27 provides a less isolated-space due to its tubular structure, $\mathbf{2 7}$ fetches $\mathrm{C}_{60}$ and forms $\mathrm{C}_{60} @ 27$ with an encapsulation yield of $88 \%$. The open structure also makes it possible to encapsulate $\mathrm{C}_{60}$ derivatives in a good yield. In addition to encapsulation, the tubular structure disassembles and releases the encapsulated $\mathrm{C}_{60}$ as well as the $\mathrm{C}_{60}$ derivatives upon irradiation. The same group has shown anisotropic-expansion of cage 26 by replacement of the phenylene backbone with naphthalene. ${ }^{[122]}$ As a consequence of self-assembly of the elongated ligand with $\mathrm{Pd}(\mathrm{II}), \mathrm{M}_{2} \mathrm{~L}_{4}$ capsule $\mathbf{2 8}$ is assembled. The larger and anisotropic cavity is capable of accommodating anisotropic fullerene $\mathrm{C}_{70}$. The anisotropic expansion of the inner cavity also facilitates the formation of apertures which are beneficial for incorporation of a C60 derivative. In a similar manner, Nitschke and co-workers constructed M4L6 tetrahedron 29 from an anthracene-based organic ligand (Figure 1.4.5b). ${ }^{[123]}$ Tetrahedral coordination cage 29 is constructed via multi-component self-assembly with $\mathrm{Fe}(\mathrm{II})$. The key feature of this reaction is the formation of the dynamic imine bonds during the self-assembly process. Dispersing $\mathrm{C}_{60}$ in an acetonitrile solution of 29 results not only in mere encapsulation of $\mathrm{C}_{60}$ but also in the intramolecular cycloadditions of three anthracenes on the confined $\mathrm{C}_{60}$ yielding 30. Interestingly, the regio-selectivity of the cycloaddition is higher than $95 \%$. In this study, the authors also performed post-assembly modification. Once 30 is treated with excess amounts of tetracyanoethylene (TCNE), three unreacted anthracene-panels undergo Diels-Alder reaction with TCNE followed by formation of 31 with $C_{3}$-symmmetry. On the other hand, Diels-Alder reaction of 29 with TCNE transforms $T$-symmetrical 29 to 32 as a mixture of diastereomers. Subsequent encapsulation of $\mathrm{C}_{60}$ inside 32 gives $T$ symmetry to maximize the contacted surfaces with $\mathrm{C}_{60}$. Intriguingly, when both encapsulation and Diels-Alder reactions are taken place in one-pot, 32 is dominantly formed because the Diels-Alder reaction is faster than the encapsulation of C60. Following this work, Nitschke and co-workers also systematically and broadly examined the accommodation capability of coordination cages $33-40$ possessing various aromatic moieties on the vertices instead of anthracene (Figure 1.4.6a).. ${ }^{[124]}$
(a)

43

(b)

Figure 1.4.7 Structure of molecular tweezers (a) 43 with X-ray structure of $\mathrm{C}_{60} @ 43$ (b) 44 for off-state and 45 for on-state (c) coordination cage 46 and schematic illustration of guest-exchange behaviour

According to the report, they found that the way the aromatic moieties are lying on the vertices is important to entrap neutral molecules inside the tetrahedral cages. Fujita and co-workers have shown endohedral functionalization of a $\mathrm{M}_{12} \mathrm{~L}_{24}$ nanoscopic sphere. ${ }^{[125]}$ Chemical modifications of the organic ligand can change the environment of the inner sphere. For instance, an organic ligand strapped with coronene forms nanoscopic cage 41 by self-assembly with $\operatorname{Pd}(I I)$ and its hydrophobic environment inside 41 is almost fully occupied with coronenes (Figure 1.4.7b). ${ }^{[126]}$ The inner cavity of 41 provides a pseudo-solvating environment for guest molecules. Owing to the ubiquitously existing coronene inside 41, C60 is solubilized within the cage. On the other hand, cage 42 whose inner space is decorated with chloronaphthalenes does not show a strong binding toward $\mathrm{C}_{60}$.

Figure 1.4.8 Structure of coordination capsules (a) 47-49 (b) $\mathbf{5 0}$ and (c) 51

Porphyrin is one of the mostly used moieties among covalently-bonded fullerenebinders because of its electronic affinity with fullerene. Reed, Boyd and co-workers reported inclusion of fullerene $\mathrm{C}_{60}$ and $\mathrm{C}_{70}$ inside 43 , in which two porphyrins are facing each other (Figure 1.4.7a). ${ }^{[127]}$ The binding constant of 43 toward $\mathrm{C}_{60}$ was determined to be $5.2 \times 10^{3} \mathrm{M}^{-1}$ in toluene by ${ }^{13} \mathrm{C}$ NMR titration. Shinkai and co-workers constructed a $\mathrm{Pd}(\mathrm{II})$-responsive bis-porphyrin $\mathrm{C}_{60}$ binder 44 and investigated its $\mathrm{C}_{60}$ encapsulation behavior (Figure 1.4.7b). ${ }^{[128]}$ The attached two pyridine coordination-sites coordinate to $\mathrm{Zn}(\mathrm{II})$ centers of the two metalloporphyrins in the "off" state. Upon addition of $\mathrm{Pd}(\mathrm{II})$, 44 turns into the "on" state 45 where the porphyrins form a sandwich-like structure similar to 20. In the "on" state, 45 is able to encapsulate $\mathrm{C}_{60}$ in a toluene $/ \mathrm{CH}_{2} \mathrm{Cl}_{2}$ solution (50:1) with an association constant of $5.1 \times 10^{3} \mathrm{M}^{-1}$, while 44 does not encapsulate $\mathrm{C}_{60}$ when it is in the "off" state. Nitschke and co-workers synthesized cubic $\mathrm{M}_{8} \mathrm{~L}_{6}$ supramolecular coordination cage 46 composed of six tetrakis-bidentate ligands and eight $\mathrm{Fe}(I I)$ centers (Figure 1.4.7c). ${ }^{[129]} 46$ encapsulates coronenes, $\mathrm{C}_{60}$ and $\mathrm{C}_{70}$ owing to six porphyrin panels offering $\pi-\pi$ interactions with those guests. Guestexchange takes place from $\mathrm{C}_{60}$ to coronenes and from $\mathrm{C}_{60}$ to $\mathrm{C}_{70}$ because the cavity size of $\mathbf{4 6}$ is more suitable to accommodate guests of higher volume than C60.

Not only planar molecules but also curved molecules are suitable moieties for the sake of fullerene-binding thanks to convex-concave interactions. Shinkai and co-workers reported in a pioneering work for coordination cages, the encapsulation of $\mathrm{C}_{60}$ utilizing calix[3]arene in 1999 (Figure 1.4.8a). ${ }^{[130]}$ Self-assembly of a calix[3]arene derivative and cis-protected $\operatorname{Pd}(I I)$ yields a $\mathrm{M}_{3} \mathrm{~L}_{2}$ molecular capsule 47. 47 forms a 1:1 $\mathrm{C}_{60-}$ inclusion complex in 1,2-tetrachloroethane solution with an association constant of 54 $\mathrm{M}^{-1}$. Fukazawa and co-workers have reported the complexation of calix[5]arene derivatives and metals (Figure 1.4.8a). ${ }^{[131,132]} \mathrm{Ag}(\mathrm{I})$ center brings two mono-2,2'-bispyridyl-functionalized tetra-p-methylcalix[5]arene to create 48 having a cavity for single $\mathrm{C}_{60} / \mathrm{C}_{70}$ encapsulation. ${ }^{[81]}$ They also demonstrated that $\mathrm{Cu}(\mathrm{I})$ as a template alters the complexation behavior between 49 and $\mathrm{C}_{60}$ from 1:2 to 1:1 fashion. On the other hand, an enhancement of the binding constant was observed for $\mathrm{C}_{70}$ in a tetrachloroethane solution. ${ }^{[82]}$ In 2004, Torres and Classen have reported subphthalocyanine-based $M_{3} L_{2}$ coordination cage 50 and showed encapsulation of $\mathrm{C}_{60}$ (Figure 1.4.8b).[ ${ }^{[133]}$ Jiang and co-workers have constructed M5L2 capsule 51 (Figure 1.4.8c). ${ }^{[134]}$ Generally, corannulene is a difficult molecule to use as a ligand because of limited possibilities of chemical modifications and its bowl inversion. ${ }^{[135]}$ The authors utilized a corannulene-based ligand having five pyridine coordination-
sites to construct cage $51 . \mathrm{PdCl}_{2}$ centers help to form the cage thanks to the transconfiguration of the vacant coordination sites. 51 preferentially encapsulates $\mathrm{C}_{60}$ over $\mathrm{C}_{70}$ in 1,2-tetrachloroethane upon heating to $130^{\circ} \mathrm{C}$. Clever and co-workers utilized a bent-shaped ligand to construct $\mathrm{Pd}_{2} \mathrm{~L}_{4}$ lantern-shaped coordination cage $\mathrm{Pd}_{2} 6_{4}$ for fullerene encapsulation (Figure 1.4.9a). ${ }^{[71]}$ The bent ligand has a nearly identical angle to triptycene which shows a good geometrical complementarity to $\mathrm{C}_{60}{ }^{[72]}$ Dispersing $\mathrm{C}_{60}$ solid in an acetonitrile solution of $\mathrm{Pd}_{2} \mathbf{6}_{4}$ results in quantitative $\mathrm{C}_{60}$ encapsulation. The authors made use of coordination-sphere-engineering by exploring ligands having a variety of coordination-sites and thus varied steric hinderance as discussed later. Recently, some metallacycles showing fullerene-encapsulation capability have been reported. For instance, metallacycle 52 having tetrathiafulvalene-backbone shows a binding constant of $1.5 \times 10^{4} \mathrm{M}^{-1}$ with $\mathrm{C}_{60}$ (Figure 1.4.9b). ${ }^{[136]}$ As another example, 53 composed of carbazole-based ligands and cis-(dppf)Pd(OTf)2 shows 1:1 molecular complex formation with $\mathrm{C}_{60}$ via $\pi-\pi$ interactions with the carbazole ligands and $\mathrm{C}_{60}$ (Figure 1.4.9c). The association constant was determined to be $K_{a}=1.0 \times 10^{5} \mathrm{M}^{-1}$ in an acetonitrile-tetrachloroethane mixture. ${ }^{[137]}$ Very recently, belt-shaped coordination cage 54 has been reported (Figure 1.4.9d). 54 is formed via metal-mediated selfassembly of cis-Pt(dppp)(OTf) $)_{2}$ and organic ligands having an electron-rich thianthrene backbone. 54 efficiently binds $\mathrm{C}_{60}$ as well as $\mathrm{C}_{70}$ with binding constant of $5.1 \times 10^{6} \mathrm{M}^{-1}$ and $3.7 \times 10^{6} \mathrm{M}^{-1}$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ in the excited states respectively determined by fluorescence spectroscopy. [138]

### 1.4.3.2 Template-effects

Figure 1.4.10 Structure of coordination cages (a) 55 (b) 56 with X-ray structure of C60@56 (c) formation of 57 (d) 58 and its X-ray structure encapsulating C6o inside

One of the most intriguing features of fullerene encapsulation inside coordination cages is unprecedented template effects. Only in the presence of fullerene as a guest, a specific topology will be formed to maximize the contacting surface between cages and fullerene via an induced fit phenomenon. As a result of repeated coordination and dissociation processes, the thermodynamically most stable host-guest complex will be obtained. Therefore, fullerene-encapsulation sometimes gives the opportunity to provide deeper insights into the thermodynamics of molecular complexes. In 2008, Schmittel and co-workers reported the synthesis of prism-shaped heteroleptic coordination cages assembled by two different organic ligands and $\mathrm{Cu}(\mathrm{I})$ metal centers (Figure 1.4.10a). ${ }^{[139]}$ In addition to the prism-shaped coordination cages, oligomeric compounds were formed. However, the formation of undesired oligomers can be suppressed in the presence of $\mathrm{C}_{60}$ as a guest molecule thanks to $\pi-\pi$ interactions with $\mathrm{C}_{60}$ and zinc-porphyrins stabilizing cage 55 . Template-effects of $\mathrm{C}_{60}$ on the formation of barrel-like coordination cage 56 was reported by Shionoya and co-workers (Figure 1.4.10b). ${ }^{[140]}$ The ligand based on metalloporphyrins carrying four bipyridyl donor-sites assembles to form a mixture of trimer and tetramer 56 upon addition of $\mathrm{Zn}(\mathrm{OTs})_{2}$ in a $\mathrm{CDCl}_{3} / \mathrm{CD}_{3} \mathrm{OD}$ (1:1) solution. By heating the solution in presence of $\mathrm{C}_{60}$, the

Figure 1.4.11 (a) Transformation from 59 to C60@60 to C60@61. X-ray structure of 59 is shown (b) Isomerization of $\mathbf{6 2}$ by template effect. X-ray structures of 62, C60@62- $T_{2}$ and $\mathrm{C}_{70} @ 62-T_{2}$ are shown (c) schematic illustration of $\mathbf{6 3}$ with its X -ray structure
equilibrium between those two conformers leans to tetramer 56 encapsulating $\mathrm{C}_{60}$ owing to the stabilization by weak interactions between $\mathrm{C}_{60}$ and the ligands. Yoshizawa and co-workers reported a C60-templated self-assembly leading to formation of a heteroleptic cage (Figure 1.4.10c). By mixing acetonitrile solutions of cage 26 and cage 28 with solid $\mathrm{C}_{60}$, the construction of heteroleptic coordination cage 57 was achieved, while only statistical mixtures are obtained without the $\mathrm{C}_{60}$ template. ${ }^{[122]}$ The same group has reported a template-effect of $\mathrm{C}_{60}$ on cage 58 (Figure
1.4.10d). Empty 58 is obtained as a mixture of regio-isomers in solution upon reacting the atropisomeric ligand with $\mathrm{Pd}(\mathrm{II}) .{ }^{[141]}$ However, upon encapsulation of $\mathrm{C}_{60}, 58$ gives a single regio-isomer where all the ligands adopt a syn-configuration via the template-
effect. This result indicates that the $\mathrm{C}_{60}$-templation can influence the equilibrium between different species but also between different regio-isomers. Nitschke and coworkers have reported the synthesis of heterometallic $\mathrm{M}_{3} \mathrm{~L}_{4}$ coordination cage 59 with the help of a template-effect by $\mathrm{C}_{60} / \mathrm{C}_{70}$ encapsulation (Figure 1.4.11a). ${ }^{[142]} \mathrm{A}$ sequential reaction of the subcomponents leads to the construction of supramolecular $\mathrm{M}_{4} \mathrm{~L}_{6}$ coordination cage 59 as a mixture of all possible diastereomers. Tetrahedral 59 transforms into cone-shaped 60 upon encapsulating fullerene, presumably due to the release of the distortion observed in the X-ray structure of 58 and weak-interactions between the ligands and the entrapped $\mathrm{C}_{60} / \mathrm{C}_{70}$. It should be noted that multi-point bonding is an essential factor to stabilize coordination cages, often seen in coordination polymer chemistry, however, one out of three Fe(II) centers loses hexacoordination while the structure undergoes reconfiguration from 59 to 60 . This result indicates existence of a template-effect. The unsaturated $\mathrm{Fe}(\mathrm{II})$ center is further replaceable with a $\mathrm{Cu}(\mathrm{I})$ center. Treatment of $\mathrm{C}_{60} / \mathrm{C}_{70} @ 60$ with $\mathrm{Cu}(\mathrm{MeCN}) 4 \cdot(\mathrm{NTf})$ yields heterometallic coordination cage 61. Phosphangulene has a bowl-shaped structure thanks to the phosphorous atom in the center. ${ }^{[143]}$ A couple of coordination cages based on phosphangulene have been reported so far. ${ }^{[144,145]}$ Due to the hindered bowl-inversion, the ligands are chiral, so are the coordination cages. Nitschke and co-workers reported M4L4 tetrahedral cage 62 by multi-component metal-mediated self-assembly (Figure 1.4.11b). ${ }^{[144]} 62$ is obtained as one of the possible diasteromers, $T_{1}$, with $P$ and $M$ chirality. Without any templates, $T_{1}-62$ is selectively formed, however, the other diastereomer $T_{2}-62$ is selectively obtained by adding $\mathrm{C}_{60}$ or $\mathrm{C}_{70}$ as a template. Nabeshima and co-workers recently discovered chirogenesis on the encapsulated $\mathrm{C}_{60}$ within chiral $\mathrm{M}_{4} \mathrm{~L}_{4}$ cage 63 composed of the chiral phosphangulene ligand and $\mathrm{Zn}(\mathrm{II})$ by chirality-transfer from the cage to the encapsulated $\mathrm{C}_{60}$ (Figure 1.4.11c). ${ }^{[145]}$ Clever and co-workers have reported a systematic study on heteroleptic assemblies by a coordination-sphere-engineering approach based on cooperative steric bulk and H-bonding around metal centers. ${ }^{[146]}$ The group has investigated self-assembly of a ligand library in which coordinationsites are diversified (Figure 1.4.12). The ligand having the quinoline coordination-sites forms bowl-shaped compound $\mathrm{Pd}_{2} 7_{3}(\mathrm{MeCN})_{2}$ by mixing with $\mathrm{Pd}(\mathrm{II})$. The steric bulk around the $\operatorname{Pd}(I I)$-centers prevents a fourth quinoline-ligand from coordination. On the other hand, a ligand possessing naphthyridine coordination-sites yields cage $\mathrm{Pd}_{2} 64_{4}$ via self-assembly with $\mathrm{Pd}(\mathrm{II})$. The coordination sites are stabilized so that the
electronic repulsion becomes minimum as can be seen in the X-ray structure. Further introduction of steric bulk around the metal centers leads to fewer ligands to coordinate.

Figure 1.4.12 Syntheses of $\mathrm{Pd}_{2} 7_{3}(\mathrm{MeCN})_{2}-\mathrm{C}_{70} @ \mathrm{Pd}_{2} 64_{1} 6_{2}(\mathrm{OAc})_{2}$. Structures of $\mathrm{Pd}_{2} 7_{3}(\mathrm{MeCN})_{2}, \quad \mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathbf{7}_{2} 64_{2}, \quad \mathrm{C}_{70} @ \mathrm{Pd}_{2} \mathbf{7 3}_{3} 642$, $\quad \mathrm{X}$-ray structures of $\mathrm{Pd}_{2} 64_{4}$, $\mathrm{Pd}_{2} 64{ }_{2}(\mathrm{Cl})_{2}, \mathrm{C}_{70} @ \mathrm{Pd}_{2} 64_{165}{ }_{2}(\mathrm{OAc})_{2}$ are shown

Self-assembly of the ligand with acridine coordination-sites and $\mathrm{Pd}(\mathrm{II})$ forms coordination ring $\mathrm{Pd}_{2} 65_{2}(\mathrm{MeCN})_{4} . \mathrm{Pd}_{2} 65_{2}(\mathrm{MeCN})_{4}$ shows a weak binding toward C60. ${ }^{[147]}$ When an equimolar amount of ligands 7 and 64 are mixed with $\operatorname{Pd}(I I)$ in
acetonitrile, an unidentifiable mixture is obtained while heteroleptic coordination cage $\mathrm{Pd}_{2} \mathbf{7}_{2} 6 \mathbf{4}_{2}$ is cleanly assembled by the template-effect with $\mathrm{C}_{60}$ in the transconfiguration. The ratio of 7 and 64 can be varied from $2: 2$ to $3: 1$. For instance, heteroleptic cage $\mathrm{Pd}_{2} \mathbf{7}_{3} 64_{1}$ can be synthesized by combining a mixture of $\mathrm{C}_{70} @ \mathrm{Pd}_{2} 7_{3}$ and $\mathrm{C}_{70} @ \mathrm{Pd}_{2} 7_{4}$ and 64 . H-bonding between the lone-pairs from the naphthyridine coordination-sites and the hydrogen atoms from the quinoline coordination-sites around the metal centers is essential for the formation of $\mathrm{Pd}_{2} 7_{3} 64_{1}$ and $\mathrm{Pd}_{2} \mathbf{7}_{2} 64$. The hydrogen atoms around $\mathrm{Pd}(\mathrm{II})$ in $\mathrm{Pd}_{2} 65_{2}(\mathrm{MeCN})_{4}$ further introduce steric bulk, preventing a third ligand to coordinate. On the contrary, the hydrogen atoms of ligand 65 together with naphthyridine ligand 64 allowed to form the first example of a heteroleptic coordination bowl $\mathrm{Pd}_{2} 64{ }_{1} 65{ }_{2}$. $\mathrm{Pd}_{2} 64{ }_{1} 65{ }_{2}$ can be yielded by mixing $\mathrm{Pd}_{2} 65_{2}(\mathrm{MeCN})_{4}$ and ligand 64.

### 1.4.3.3 Encapsulation of multiple fullerenes

X-ray structures of 71, 72, and ( $\left.\mathrm{C}_{60}\right)_{2} @ 73$ are shown (e) structure of (C60)4@59 on the left side and X-ray structure of (C60)3@59

Multi-substrate encapsulation is a ubiquitous and important function in biological systems. ${ }^{[61]}$ To understand this phenomenon, mimicking and developing a molecular system accommodating multiple guest molecules are of importance. ${ }^{[61]}$ Furthermore, fullerenes trapped and well-aligned in close proximity is of great interest in solid-state physics. ${ }^{[24,27]}$ Until recently, only few coordination cages incarcerating more than one
$\mathrm{C}_{60 \mathrm{~s}}$ have been reported. The first example of encapsulating multiple C 60 s within a coordination cage was reported by Würthner and co-workers (Figure 1.4.13a). ${ }^{[148]}$ They have chosen a perylene bisimide (PBI) based organic ligand in order to construct a supramolecular coordination cage. Tetrahedral $M_{4} L_{6}$ cage 66 is formed by reacting the organic ligand and $\mathrm{Fe}(\mathrm{II})$ metal source in an acetonitrile/ $\mathrm{CHCl}_{3}$ (1:1) solution. The inner cavity volume of cage 66 was calculated to be 950-2150 $\AA^{3}$ while the volume of $\mathrm{C}_{60}$ is estimated to be $597 \AA^{3}$. The large and hollow cavity of 66 is therefore suitable to accommodate several counts of $\mathrm{C}_{60}$. After mixing 66 and an excess amount of $\mathrm{C}_{60}$ in acetonitrile/ $\mathrm{CHCl}_{3}$ (9:1), according to ${ }^{13} \mathrm{C}$ NMR analysis of $\mathrm{C}_{60} @ 66$ in an acetonitrile solution, encapsulation of one molecule of $\mathrm{C}_{60}$ was observed. On the other hand, an ESI-MS spectrum showed not only C60@66 but also (C60)2@66, which is indicative of accommodation of two $\mathrm{C}_{60}$ S in the gas phase. Considering the empirical " $55 \%$ occupancy theory" postulated by Rebek, ${ }^{[149]}$ encapsulation of two $\mathrm{C}_{60}$ molecules is in agreement with this theory. Yoshizawa and co-workers reported encapsulation of two molecules inside $M_{3} L_{4}$ coordination cage 67 (Figure 1.4.13b). ${ }^{[150]}$ The ligand having three pyridine coordination-sites and four anthracene panels yields assembly 67 by treatment with $\mathrm{Pd}(\mathrm{II})$ in DMSO at $110{ }^{\circ} \mathrm{C} .67$ provides two independent isolated spaces, and therefore, two $\mathrm{C}_{60}$ molecules were assumed to be encapsulated in these voids. Intriguingly, coordinate bonds at the central Pd(II) center spontaneously break to expand the isolated spaces in order to accommodate two $\mathrm{C}_{60}$ s and form peanutshape coordination cage 68 after release of a Pd(II) cation. These expanded inner cavities can incarcerate not only two $\mathrm{C}_{60}$ s but also two $\mathrm{C}_{70}$ S and two $\mathrm{Sc}_{3} \mathrm{~N} @ \mathrm{C}_{80}$ S. These results demonstrate the flexibility of the cavities. Notably, the flexible cavities make it possible to encapsulate two different guest-molecules with a different size, in which a smaller cavity is occupied with adamantane while a larger cavity is occupied by two phenanthrene molecules. By replacing the central pyridine group with benzene, another supramolecular array was further obtained. ${ }^{[151]}$ In contrast to 67, M2L4 peanutshaped coordination cage 70 can be synthesized at room temperature. The W-shaped organic ligand displays a solvent-dependent assembly. In DMSO in the presence of $\operatorname{Pd}(I I)$, a mononuclear ML2 coordination compound 69 forms with both ligands folding back to coordinate the single $\mathrm{Pd}(\mathrm{II})$ in a chelating mode, while $\mathrm{M}_{2} \mathrm{~L}_{4}$ cage 70 forms in an acetonitrile/ $\mathrm{H}_{2} \mathrm{O}$ (9:1) solution (Figure 1.4.13c). $\mathrm{M}_{2} \mathrm{~L}_{4}$ cage 70 can encapsulate two $\mathrm{C}_{60}$ molecules at room temperature, whilst addition of $\mathrm{C}_{60}$ into the DMSO solution of 69 yields the formation of the same (C60)2@70 in virtue of a template effect.

Figure 1.4.14 (a) Diels-Alder reaction between encapsulated $\mathrm{C}_{60}$ inside $\mathrm{Pd}_{2} 7_{3}(\mathrm{MeCN})_{2}$; X-ray structures are shown for $\mathrm{C}_{60} @ \mathrm{Pd}_{2} 7_{3}(\mathrm{MeCN})_{2}$ and C60ant@Pd $\mathbf{7}_{3} \mathrm{Cl}_{2}$ (b) X-ray structure of $\mathrm{C}_{70} @ \mathrm{Pd}_{2} 7_{4}$ and (c) (C60) ${ }_{2} @ \mathrm{Pd}_{4} \mathrm{Cl}_{6}(\mathrm{TPA})_{2}$

Cyclic voltammetry highlighted that each encapsulated C60s within an analogue of 70 show different reduction potentials although they are not in direct contact. Nitschke and co-workers reported incorporation of two $\mathrm{C}_{60}$ s inside $S_{6}$-symmetric polyhedral 73 (Figure 1.4.13d). ${ }^{[152]}$ In this study, a template-effect helps re-organization of ( $\left.\mathrm{C}_{60}\right)_{2} @ 73$ from either $O$-symmetric polyhedral 71 or $D_{4}$-symmetric polyhedral 72. Notably, in the $O$-symmetric structure, 71 shows negative cooperativity in binding of $\mathrm{B}_{12} \mathrm{~F}_{12}{ }^{2-}$, whilst ( $\mathrm{C}_{60}$ ) ${ }_{2}$ @73 showcases the cage-to-cage transformation and the allosteric binding behavior with a $\mathrm{C}_{70}$ s encapsulating species as well. The same group reported encapsulation of up to four molecules of fullerene into 59 and investigated electronic properties of the confined $\mathrm{C}_{60}$ s closely contacting each other. ${ }^{[153]} 59$ was shown to undergo reconstitution to cone-shaped 60 templated by $\mathrm{C}_{60}{ }^{[142]}$ in acetonitrile, yet, the $M_{4} L_{6}$ structure is maintained in less coordinative solvents such as $\mathrm{MeNO}_{2}$ or $\mathrm{PhNO}_{2}$. The encapsulation behavior was also found to be different in both solvents. Up to three $\mathrm{C}_{60}$ s can be accommodated in 59 in $\mathrm{MeNO}_{2}$, while up to four $\mathrm{C}_{60}$ s can be accommodated in 59 in $\mathrm{PhNO}_{2}$. Cyclic voltammetry revealed the existence of electronic communication between the closely packed $\mathrm{C}_{60}$ s. In another work, Clever and co-workers constructed a pill-shaped coordination cage encapsulating two $\mathrm{C}_{60}$ molecules. Coordination-sphere engineering enables the formation of bowl-shaped $\mathrm{Pd}_{2} 7_{3}(\mathrm{MeCN})_{2}$ in which acetonitrile molecules are coordinating one of the coordination sites of each $\mathrm{Pd}(\mathrm{II})$ cation (Figure 1.4.14). Treatment of $\mathrm{Pd}_{2} 7_{3}(\mathrm{MeCN})_{2}$ with two equivalents of terephthalate (TPA) creates pillshaped cage $\mathrm{Pd}_{4} \mathrm{~F}_{6}(\mathrm{TPA})_{2}$ whilst addition of $\mathrm{C}_{70}$ leads to a mixture of
$\mathrm{C}_{70} @ \mathrm{Pd}_{2} 7_{3}(\mathrm{MeCN})_{2}$ and $\mathrm{C}_{70} @ \mathrm{Pd}_{2} 7_{4}$. $\mathrm{C}_{60} @ \mathrm{Pd}_{2} 7_{3}(\mathrm{MeCN})_{2}$ also shows the same dimerization behavior. As a result of the dimerization of $\mathrm{C}_{60} @ \mathrm{Pd}_{2} 7_{3}(\mathrm{MeCN})_{2}$, $\left(\mathrm{C}_{60}\right)_{2} @ \mathrm{Pd} 4 \mathrm{H}_{6}(\mathrm{TPA})_{2}$ is assembled. ${ }^{[71]}$

### 1.4.3.4 Selective encapsulation of fullerenes

(a)

$$
\mathrm{R}=-\left(\mathrm{OC}_{2} \mathrm{H}_{4} \mathrm{OCH}_{3}\right)
$$

75

Figure 1.4.15 Cage-to-cage transformation between 74 and 75 by addition of metal/ligand. X-ray structure of 75, (b) X-ray structure of 76 and 77

On account of a demand for facile and environment friendly fullerene purification methods, size selective encapsulation of fullerenes is of great interest. Some of the state-of-the-art molecular designs of covalently-bonded fullerene-binders showing selectivity for specific fullerenes have been introduced already in above sections. A geometrical and spatial matching is one of the most important factors to determine if fullerene-binders have special preferences for selected fullerenes. Among the coordination cages introduced already, for instance, Yoshizawa's molecular capsule 27 selectively binds $\mathrm{C}_{60}$ out of carbon-soot and releases the captured $\mathrm{C}_{60}$ upon light irradiation. ${ }^{[121]}$
(a)

(b)

79
(f)

$83\left(=\right.$ cis- $\left(\mathrm{PEt}_{3}\right)_{2}$

Figure 1.4.16 (a) Dimerization of macrocycles to form $\mathbf{7 8}$ (b) structures of $\mathbf{7 9}$ (c) $\mathbf{8 0}$ (d) and 81 with its X-ray structure (e) X-ray structures of $\mathbf{8 2}$ and $\mathrm{C}_{70} @ \mathrm{Pd}_{2} 7_{4}$ (f) structure of 83

In addition, the anthracene ligand mixed in 2:1 ratio with $\mathrm{Hg}(\mathrm{II})$ gives $\mathrm{Hg}_{2} \mathrm{~L}_{4}$ capsule 74 while ring-shaped 75 is formed when the ratio is $1: 1$ (Figure 1.4.15a). ${ }^{[154]}$ While 74 can bind either $\mathrm{C}_{60}$ or $\mathrm{C}_{70}, \mathbf{7 5}$ cannot. In addition, $\mathbf{7 4}$ preferably encapsulates $\mathrm{C}_{60}$ over $\mathrm{C}_{70}$. By exploiting these features, uptake and release of $\mathrm{C}_{60} / \mathrm{C}_{70}$ can be performed by changing the $\mathrm{Hg}(\mathrm{II})$-to-ligand ratio. Cubic coordination cage 46 reported by Nitschke's group shows a preference to bind larger fullerenes, e.g., $\mathrm{C}_{70}, \mathrm{C}_{76}$ and $\mathrm{C}_{84}$, over $\mathrm{C}_{60}$ according to ESI-MS analyses. ${ }^{[129]}$ Corannulene-based coordination cage 51 reported by Jiang shows selective encapsulation of $\mathrm{C}_{60}$ over $\mathrm{C}_{70}$ upon temperature increase as introduced before. ${ }^{[134]}$ In addition to those works, Gu and co-workers have reported selective encapsulation of $\mathrm{C}_{60}$ in M4L6 coordination cages 76 and 77 composed of $\mathrm{Fe}(\mathrm{II})$ centers and flexible organic ligands (Figure 1.4.15b). ${ }^{[155]}$ Recently $\mathrm{C}-\mathrm{H} \cdot \cdots{ }^{\circ}$
interactions have been found to be versatile weak interactions to create unique supramolecular arrays. An elaborate molecular design even makes the construction of fullerene-inclusion molecular complexes possible utilizing $\mathrm{C}-\mathrm{H} \cdot \cdots{ }^{\circ} \mathrm{\pi}$ interactions. ${ }^{[115,116,156]}$ As an example of such supramolecular complexes, Tanaka and co-workers reported double-decker type coordination cage 78 (Figure 1.4.16a). ${ }^{[157]}$ Bridging two macrocycles by DABCO gives 78 in $\mathrm{CDCl}_{3} .78$ can encapsulate $\mathrm{C}_{70}$ within the central hole of the macrocycles via C-H $\cdots$ interactions. 78 forms a $1: 1$ molecular complex with $\mathrm{C}_{70}$ in a $\mathrm{CHCl}_{3} / \mathrm{CS}_{2}$ (5:2) solution with an encapsulation yield of $22 \%$. The $K_{a}$ value was determined to be $180 \mathrm{M}^{-1}$ by a ${ }^{1} \mathrm{H}$ NMR study. The authors claimed that multiple $\mathrm{C}-\mathrm{H} \cdots{ }^{\circ} \boldsymbol{\pi}$ interactions should be the key for encapsulation. Peris and coworkers have shown preferable encapsulation of $\mathrm{C}_{70}$ within prism-shaped coordination cage 79 via $\pi-\pi$ interactions (Figure 1.4.16b). ${ }^{[158]}$ Self-assembly of a bis-nickel-pyrene-di-imidazolylidene complex and 1,3,5-tripyridyl-triazine in the presence of $\mathrm{AgBF}_{4}$ yields the prism-shaped cage. The pillars possessing aromatic pyrene moieties enable $\pi-\pi$ interactions with fullerenes. 79 is capable of encapsulating $C_{60}$ and $C_{70}$, however, $\mathrm{C}_{70}$ shows more favorable interactions compare to $\mathrm{C}_{60}$. DFT calculations suggest that the replacement from $\mathrm{C}_{60} @ 79$ to $\mathrm{C}_{70} @ 79$ should be an exergonic process. The pyrene-di-imidazolylidene ligand also forms box-shaped complex 80 upon reaction with allylpalladium(II) chloride dimer (Figure 1.4.16c). ${ }^{[159,160]} \mathbf{8 0}$ displays selective encapsulation of $\mathrm{C}_{70}$ thanks to the one order of magnitude higher association constant with $\mathrm{C}_{70}$ over $\mathrm{C}_{60} .80$ shows the adjustment of the size of the cavity depending on the guest molecules in the solid state. $\mathrm{C}_{60}$ and $\mathrm{C}_{70}$ are known to have a property to generate ${ }^{1} \mathrm{O}_{2}$ by triplet-triplet energy transfer from ${ }^{3} \mathrm{C}_{60} /{ }^{3} \mathrm{C}_{70}$ to ${ }^{3} \mathrm{O}_{2}$. ${ }^{[161]}$ The encapsulated $\mathrm{C}_{60} / \mathrm{C}_{70}$ within 80 has the inherited property even under confinement and promotes a hetero Diels-Alder reaction with in situ generated ${ }^{1} \mathrm{O}_{2}$. The adaptability of the cage was further investigated also in the gas-phase using ion mobility mass spectrometry. ${ }^{[162]}$ Based on their previous works, Nitschke and co-workers synthesized cubic coordination cage 81 composed of six $\mathrm{Ni}(\mathrm{II})$-porphyrin based ligands and eight $\mathrm{Fe}(\mathrm{II})$ ions (Figure 1.4.16d). ${ }^{[163]}$ Single crystal X-ray structural analysis confirms the pseudo-O-symmetric structure with a large cavity of $3183 \AA^{3}$. In virtue of the large inner cavity and the large deviation from the Rebek's $55 \%$ rule, mere $\mathrm{C}_{60}$ as well as some large anions are not suitable as guest molecules. The encapsulation of fullerene adducts synthesized via Diels-Alder reaction with either anthracene or indene were tested in an acetonitrile solution of the cage by suspending
the adducts. The experiments showed that only the bis-adduct could be encapsulated within 81. Clever and co-workers have reported size-selective encapsulation of $\mathrm{C}_{60}$ and $\mathrm{C}_{70}$ inside $\mathrm{Pd}_{2} \mathrm{~L}_{4}$ cavities by coordination-sphere engineering. ${ }^{[71,147]}$ Depending on the coordination-sites, the size of a cavity can be modified. For instance, cage $\mathrm{Pd}_{2} 6_{4}$ selectively binds $\mathrm{C}_{60}$, however, cage $\mathrm{Pd}_{2} 7_{4}$ possessing a larger cavity can bind $\mathrm{C}_{70}$ (Figure 1.4.16e). These results imply that the position of the N -atoms on the quinoline coordination-sites also influences the encapsulation ability. 82 encapsulates neither $\mathrm{C}_{60}$ nor $\mathrm{C}_{70}$ due to its relatively small cavity. Stang and co-workers have recently reported prism-shaped coordination cage 83 by metal-mediated self-assembly of a PDI-based ligand and cis-(PEt $\left.)_{2}\right)_{2} \mathrm{Pt}(\mathrm{OTf})_{2}$ (Figure 1.4.16f). ${ }^{[164]} 83$ selectively encapsulates $\mathrm{C}_{70}$ out of a $\mathrm{C}_{60}$ and $\mathrm{C}_{70}$ mixture.

### 1.4.3.5 Purification of fullerenes

One of the ultimate goals of the selective binding of a specific fullerene is to develop a purification system. The first example of fullerene-purification using a supramolecular approach was reported by Shinkai and Atwood. ${ }^{[74,75]}$ In their approach, a calix[8]arene derivative can selectively encapsulate $\mathrm{C}_{60}$ out of other higher fullerenes and the encapsulated $\mathrm{C}_{60}$ can be released by a simple solvent treatment. Coordination cages which can selectively encapsulate a specific fullerene have attracted attention in terms of fullerene purification as coordination cages are relatively easy to synthesize and are assembled via rather labile coordinative bonds which are advantageous for uptake-and-release. Shinkai and co-workers reported metallo-supramolecular fullerene-binder 47 in 1999, ${ }^{[130]}$ and nano-capsule 47 has been proven to exhibit alkalimetal responsive $\mathrm{C}_{60}$ uptake/release behavior. ${ }^{[165]}$ The $K_{a}$ value for the formation of the $1: 1$ host-guest complex $\mathrm{C}_{60} @ 47$ is $54 \mathrm{M}^{-1}$ in 1,2-dichloroethane at 298 K . Besides the binding abilities of the central cavity, the peripheral ester chains in proximity capture small cations such as $\mathrm{Li}^{+}$and $\mathrm{Na}^{+}$. Addition of $\mathrm{Li}^{+}$cations induce the adjacent of phenyl groups to become more flattened, thus altering the shape and size of the central cavity.

(b)

(c)

C60@89

90

Figure 1.4.17 (a) partial structure of coordination polymer 84 (b) structure of 85-88 (c) ejection and encapsulation of $\mathrm{C}_{60}$ through formation and deformation of $\mathrm{C}_{60} @ 89$ and 90

The resulting cavity of $2 \mathrm{Li}+\bullet 47$ is more suitable for the encapsulation of globular $\mathrm{C}_{60}$, resulting in the enhanced $K_{a}$ values up to $2100 \mathrm{M}^{-1}$. In stark contrast, when the larger cations, $\mathrm{Na}^{+}$, are bound to the ester pockets, a significant decrease of $K_{a}$ value is observed. Accordingly, the cation-induced adjustment on binding affinities of this host is employed to realize $\mathrm{C}_{60}$ uptake/release in a reversible fashion. Note that 47 does not show encapsulation toward $\mathrm{C}_{70}$ which is a criterion for purification of $\mathrm{C}_{60}$. Fujita and co-workers showcased accommodation of fullerenes into the 3D network of porous coordination polymer 84, hinged by Co(II) centers (Figure 1.4.17a). ${ }^{[166]}$ Single crystal X-ray structure analysis revealed that 84 has a cuboctahedral unit. Owing to the hierarchical structure, coordination polymer 84 has large apertures allowing encapsulation of fullerene in the crystalline state by soaking a toluene solution of fullerenes. Acid treatment of the host-guest crystals is required to recover the stored fullerenes. Due to the huge cavities, larger fullerenes are more prone to be captured than smaller ones enabling enrichment of $\mathrm{C}_{70}$ from commercially available carbon-
soot. Ribas and co-workers have also developed a C60 purification method out of crude carbon-soot containing higher fullerenes by washing solids of $\mathrm{C}_{60}$-inclusion coordination cage 85 with an organic solvent (Figure 1.4.17b). ${ }^{[167]}$ Tetragonal prismshaped coordination cage 85 is synthesized via self-assembly of two molecules of tetracarboxylate $\mathrm{Zn}(\mathrm{II})$-porphyrin and four molecules of a readily prepared $\mathrm{Pd}(\mathrm{II})$ based macrocyclic synthone in acetonitrile. Large apertures allowing solvation of confined fullerenes often result in small binding constants, however, a strong affinity of the metalloporphyrins with fullerene compensates the poor binding ability. ${ }^{[99]}$ In fact, 85 forms $1: 1$ molecular complex with $\mathrm{C}_{60}$ with $K_{a}$ value of $2.8 \times 10^{7} \mathrm{M}^{-1}$, although 85 has four apertures allowing solvent molecules to reach the confined $\mathrm{C}_{60}$. A variety of fullerenes including $\mathrm{C}_{60}, \mathrm{PC}_{61} \mathrm{BM}, \mathrm{C}_{70}$ and $\mathrm{C}_{84}$ can be bound within prismatic cage 85 in $1: 1$ ratio and the larger fullerene tends to display a higher affinity with 85 . The accommodation of a fullerene causes a shrinkage of the cage to maximize contacting surfaces. The lower binding ability of 85 for $\mathrm{C}_{60}$ relatively to larger fullerenes realizes a facile and selective release of the encapsulated $\mathrm{C}_{60}$ by a washing process. Solid sample of fullerenes encapsulating 85 are precipitated by addition of diethylether to an acetonitrile/toluene (1:1) solution of 85 and fullerene-extracts from carbon-soot. By washing the solid sample with CS2/o-dichlorobenzen (1:1), only C60 is liberated while the other encapsulated higher fullerenes can be released by acid treatment. This encapsulating-washing protocol is repeatable with the same sample and the strategy has potential to simplify fullerene-purification. Not only the solvent-washing strategy is applicable to release the confined $\mathrm{C}_{60}$ but also competitive guest-uptake can release the $\mathrm{C}_{60}$ as following. ${ }^{[168]}$ The same group demonstrated recovery of the encapsulated $\mathrm{C}_{60}$ in 85 by encapsulation of a two-electron-oxidation active compound, tetrapyridyl-extended-tetrathiafulvalene (exTTF)-based ligand ( $m$-Py)exTTF. In a neutral state ( $m$ Py)exTTF is in a bent-shape and is able to anchor $\mathrm{Zn}(\mathrm{II})$ centers from inside the cage. Upon two-electron oxidation, (m-Py)exTTF becomes flat and escapes outside. C60 uptake and release can be performed accompanying the reduction/oxidation process. The size of the prismatic cage can be tuned by changing linkers. Replacement of the biphenyl linkers to naphthalene linkers changes the $\mathrm{Zn}-\mathrm{Zn}$ distance of the porphyrin from $14.1 \AA$ to $8.2 \AA$ according to the X-ray structures. ${ }^{[169]}$ Although the $\mathrm{Zn}-\mathrm{Zn}$ distance is smaller than the diameter of $\mathrm{C}_{60}, 87$ can encapsulate $\mathrm{C}_{60}$ and even $\mathrm{C}_{70}$. MD simulations suggest the adaptability of 87 derives from the flexibility of the cage. Contrary to cage 85, naphthalene-linked cage 87 shows exclusive encapsulation of
$\mathrm{C}_{60}$ out of a fullerene mixture containing $\mathrm{C}_{60}, \mathrm{C}_{70}$ and other bigger fullerenes. 87 can also encapsulate fullerene $\mathrm{C}_{60}$ derivatives, $\mathrm{PC}_{61} \mathrm{BM}$ and N -pyrrolidine- $\mathrm{C}_{60}$, in a $1: 1$ ratio. Interestingly, cage 87 shows a slightly lower $K_{a}$ value towards both $\mathrm{C}_{60}$ derivatives compared to $\mathrm{C}_{60}$. Only weakly bound N -pyrrolidine- $\mathrm{C}_{60}$ can be liberated by the solvent-washing strategy. The strong binding ability of cage 85 to higher fullerenes realizes a simple purification of $\mathrm{C}_{60}$, higher fullerenes, and even endohedral metallofullerenes (EMFs). In this study, Ribas and co-workers tried purification of endohedral metallofullerenes (EMFs) by utilizing 86, an $\mathrm{Cu}(\mathrm{II})$ analogue of 85. [170] When the encapsulation of fullerenes extracted from carbon-soot containing $\mathrm{C}_{60}, \mathrm{C}_{70}$, $\mathrm{Sc}_{3} \mathrm{~N}^{2} \mathrm{C}_{68}, \quad \mathrm{Sc}_{3} \mathrm{~N} @ \mathrm{C}_{78}, \quad \mathrm{Sc}_{3} \mathrm{~N} @ \mathrm{C}_{80}$ and other fullerenes is performed in a toluene/acetonitrile (9:1) solution, $1: 1$ complexes of 86 incarcerating $\mathrm{C}_{60}$, $\mathrm{C}_{70}$, $\mathrm{Sc}_{3} \mathrm{~N} @ \mathrm{C}_{68}, \mathrm{Sc}_{3} \mathrm{~N} @ \mathrm{C}_{78}, \mathrm{Sc}_{3} \mathrm{~N} @ \mathrm{C}_{80}$ are mainly obtained. Notably, all encapsulated species can be liberated through the solvent-washing protocol. In stark contrast, 86 shows a preferential encapsulation-behavior for smaller fullerenes when solid 86 is soaked into the fullerene mixture in a toluene solution. By taking advantage of this, $\mathrm{Sc}_{3} \mathrm{~N} @ \mathrm{C}_{80}$ can be selectively obtained by capturing other smaller fullerenes. As a result, only $\mathrm{Sc}_{3} \mathrm{~N} @ \mathrm{C}_{80}$ remains in the toluene solution, whilst the other smaller fullerenes are entrapped in $\mathbf{8 6}$. Surprisingly, 86 is also able to purify $\mathrm{U}_{2} @ I_{h}-\mathrm{C}_{80}$ and Sc2CU@ $l_{h}$ - C 80 from carbon-soot one by one each. ${ }^{[171]}$ In stark contrast to $\mathrm{Sc}_{3} \mathrm{~N} @ \mathrm{C}_{80}$, both $\mathrm{U}_{2} @ I_{h}$ - $\mathrm{C}_{80}$ and $\mathrm{Sc}_{2} \mathrm{CU} @ l_{h}$ - $\mathrm{C}_{80}$ are extracted by mixing solid-state 86 and a toluene solution of EMFs and empty fullerenes mixture. When crystalline 86 is soaked in a toluene solution of a carbon-soot containing $\mathrm{U}_{2} @ \mathrm{C}_{80}, \mathrm{Sc}_{2} \mathrm{CU} @ I_{h}-\mathrm{C}_{80}$ and other fullerenes, $\mathrm{U}_{2} @ \mathrm{C}_{80}$ is selectively encapsulated. Repetitive soaking of 87 to the remaining supernatant results in the removal of $\mathrm{Sc}_{2} \mathrm{CU@} l_{h}-\mathrm{C}_{80}$ as $\mathrm{Sc}_{2} \mathrm{CU@} l_{h}-\mathrm{C}_{80}$ is entrapped within the cage. 87 even shows the selective encapsulation for $\mathrm{U}_{2} @ l_{h}$ - $\mathrm{C}_{80}$ over $\mathrm{Sc}_{2} \mathrm{CU}$ @ $l_{h}-\mathrm{C}_{80} .86$ also shows a favorable encapsulation behavior to EMFs, $\mathrm{U}_{2} @ \mathrm{C}_{78}$ and $\mathrm{U}_{2} \mathrm{C} @ \mathrm{C}_{78}$, possessing a slightly different carbon cage from $\mathrm{U}_{2} @ I_{h^{-}}$ C80. ${ }^{[172]}$ The adaptability of 86 allows specific molecular recognition. 86 can tell apart from $\mathrm{U}_{2} @ \mathrm{C}_{78}$ and $\mathrm{U}_{2} \mathrm{C} @ \mathrm{C}_{78}$ depending on the encapsulated species within the fullerene. The trapped guest molecules can be released by washing the crystalline host-guest complex with $\mathrm{CS}_{2}$. Elongation of the cavity size by replacing the biphenyl linkers by diphenylacetylene linkers makes the selective encapsulation of $\mathrm{C}_{84}$ possible. ${ }^{[173]}$ The content of $\mathrm{C}_{84}$ in the recovered guests can be increased $\sim 125$-fold compared with the one in the initial carbon-soot by purification utilizing 88. The
detailed dynamic behavior of the adaptability of cage 85 was investigated by combination of ${ }^{1} \mathrm{H}-{ }^{1} \mathrm{H}$ exchange spectroscopy (2D-EXSY) NMR experiments, long time-scale Molecular Dynamics (MD) and accelerated Molecular Dynamics (aMD) simulations. ${ }^{[174]}$ Nitschke and co-workers reported fuel-controlled reassembly of macrocycle 89 accompanied by $\mathrm{C}_{60}$ uptake and release (Figure 1.4.17c). ${ }^{[175]}$ When 89 is mixed with triphenylphosphine (TPP), TPP coordinates $\mathrm{Cu}(\mathrm{I})$ and thus replaces the Ni-porphyrin ligands to yield 90 . As a consequence of the ligand exchange, the encapsulated $\mathrm{C}_{60}$ is released from the macrocycle. In the presence of a rhenium catalyst and pyridine N -oxide, TPP is oxidized to triphenylphosphineoxide presenting lower coordination ability than TPP. Thus, 91 gradually transforms into 89 over time and encapsulates $\mathrm{C}_{60}$ inside the macrocycle when 90 is treated under oxidation conditions.

### 1.4.3.6 Reaction of $\mathrm{C}_{60}$ inside coordination cages

Fullerene derivatives have been utilized in the field of photovoltaics and molecular electronics. The electron-accepting ability and the unique structure are a great advantage as an electron-accepting material. ${ }^{[176-178]}$ However, regio-selective chemical modification of $\mathrm{C}_{60}$ require a special strategy. ${ }^{[29,179,180]}$ Fullerene-binders such as coordination cages can help regioselective modifications of $\mathrm{C}_{60}$ as a supramolecular mask as nicely summarized in the literature. ${ }^{[180]}$ Clever and coworkers have showcased a Diels-Alder reaction between confined $\mathrm{C}_{60}$ and anthracene. ${ }^{[71]}$ Bowl-shaped $\mathrm{Pd}_{2} 7_{3}(\mathrm{MeCN})_{2}$ covers ca. $75 \%$ of the surface of the incarcerated $\mathrm{C}_{60}$, and thus, Diels-Alder reaction takes place only on the uncovered surface to give only the mono-adduct. Mixing $\mathrm{C}_{60} @ \mathrm{Pd}_{2} 7_{3}(\mathrm{MeCN})_{2}$ and 10 equivalents of anthracene in acetonitrile gives only mono-adduct of fullerene (Figure 1.4.14). As mentioned above, Nitschke and co-workers have demonstrated the chemo-selective formation of the bis-adduct of $\mathrm{C}_{60}$ and anthracene/indene using 81 (Figure 1.4.18a). Stimulated by this work, a metal-organic framework which catalyzes the same DielsAlder reaction with $\mathrm{C}_{60}$ and anthracene yielding only $\mathrm{C}_{60}$-anthracene bis-adduct was developed. ${ }^{[181]}$ Ribas and co-workers reported a regio-selective Bingel-Hirsch reaction by utilizing metallo-supramolecular complex 85 as a supramolecular mask. ${ }^{[182,183]}$ The structure of 85 possessing four large apertures allows nucleophiles to access the bound $\mathrm{C}_{60}$ and controls the regio-selectivity.

Figure 1.4.18 (a) Selective formation and encapsulation of $\mathrm{C}_{60}$ Diels-Alder bis-adducts inside 81, (b) Regio-selective Bingel-Hirsch reaction on the encapsulated $\mathrm{C}_{60}$ inside C60@85, (c) X-ray structure of [10]CPP@C60@88 and utilization of the molecular complex for regio-selective synthesis of $\mathrm{C}_{60}$ trans-bis-adduct.

When $\mathrm{C}_{60}$ encapsulating coordination cage 85 is treated in the Bingel-Hirsch reaction condition, cage 85 serves as a protecting group leading to the regioselective multiaddition reaction on the encapsulated $\mathrm{C}_{60}$ (Figure 1.4.18b). As a consequence, four malonate substituents are introduced on the equator of the encapsulated $\mathrm{C}_{60}$. It was elucidated that the Bingel-Hirsch reaction takes place step-by-step by ESI-MS analysis. This stepwise process realizes a one-pot synthesis of hetero-tetrakis adducts and hetero-hexakis adducts. The regioselective functionalization reaction can be performed under cyclic turnover conditions. Addition of excess amounts of sulfate triggers anion metathesis and the transfer of the cage into the water layer of a reaction
mixture takes place. Then after, the Bingel-Hirsch reaction proceeds in the aqueous phase. Once the reaction finished, the host-guest complex is carried back to the organic layer by the addition of tetraarylborates. In the organic layer, the tetrakisadduct is replaced by intact $\mathrm{C}_{60}$. It should also be noted that all the reactions introduced in this section can be performed in polar media, which are usually not employed for chemical reactions of $\mathrm{C}_{60}$ due to its poor solubility. Very recently, Ribas, von Delius and co-workers further extended the regio-selective Bingel-Hirsch reaction (Figure 1.4.18c). A Russian-doll like molecular complex was synthesized by encapsulation of a molecular complex of $\mathrm{C}_{60}$ and [10]CPP inside 88/91. ${ }^{[184]}$ The solidstate structure of C60@[10]CPP@88 was elucidated by single crystal X-ray structure analysis. The encapsulated $\mathrm{C}_{60} @[10] \mathrm{CPP}$ complex was found to tilt against the $\mathrm{Zn}-\mathrm{Zn}$ axis. The introduction of further molecular hindrance around $\mathrm{C}_{60}$ together with the tilted geometry leads the exclusive formation of trans-bis-adducts. In addition to those examples, a couple of advanced reactions of $\mathrm{C}_{60}$ inside coordination cages have been reported. ${ }^{[185,186]}$

### 1.4.3.7 Electronic/Magnectic interactions

Electronic/Magnetic communication within supramolecular systems including fullerenes is one of the greatest interests as it plays a significant role in artificial photosynthesis, ${ }^{[187,188]}$ molecular magnetism, ${ }^{[155,189]}$ and charge separation. ${ }^{[190]}$ Electronic properties of organic ligands may give rise to perturbations on confined fullerenes and thus, physical properties of fullerenes are tunable by a nanoconfinement effect. Nitschke and co-workers have demonstrated an enhanced catalytic activity of $\mathbf{9 2}$ for oxidative coupling of arylborates by incarceration of $\mathrm{C}_{60}$ (Figure 1.4.19a). ${ }^{[191]}$ The redox-activity of 92 is inherited from the redox-active NDI ligand incorporated in the cage structure. Redox-active 92 catalyzes oxidative coupling of a tetraarylborate to give a homo-coupling product. Addition of $\mathrm{C}_{60}$ improves the catalytic efficiency. The author concluded that the improvement should derive from the stabilization of radical species of the ligand by the encapsulated $\mathrm{C}_{60}$. On the other hand, cationic NDI-based coordination cage 93 does not entrap neutral $\mathrm{C}_{60}$ due to electronic repulsions. ${ }^{[192]}$ However, reduction of the NDI-backbone decreases the

Figure 1.4.19 (a) Structures of 92 and 93; X-ray structure of 93 is shown. Reaction catalysed by 92 is shown below the structures (b) Structure of 94 and its X-ray structure (c) X-ray structure of 95
repulsion with $\mathrm{C}_{60}$ and thus $\mathrm{C}_{60}$ can be incarcerated only in the reduced-state. When 93 is treated with $\mathrm{Cp}_{2} \mathrm{Co}$, the reduced cage encapsulates $\mathrm{C}_{60}$. Addition of $\mathrm{Ag}(\mathrm{NTf})$ oxidizes reduced 93 leading to ejection of $\mathrm{C}_{60}$ from the cage over time. Phase-transfer from the acetonitrile solution to water by anion-metathesis also initiates the ejection of $\mathrm{C}_{60}$ from 93. Lützen and co-workers have reported stabilized high-spin state Fe (II) centers by accommodation of $\mathrm{C}_{70}$ inside cage 94 (Figure 1.4.19b). ${ }^{[155,189]}$ As a result of the stabilized high-spin state in virtue of $\mathrm{C}_{70}$ inside, the phase-transition temperature of the spin-crossover becomes lower. The authors attributed the stability to entropic effects. Cages 76 and 77 , reported by Gu and co-workers, also show the stabilized high-spin state of the $\mathrm{Fe}(\mathrm{II})$ centers by inclusion of $\mathrm{C}_{60}$ in the solid-state. Nitschke and co-workers reported coordination cage 95 consisting of an antiaromatic building block, $\mathrm{Ni}(I I)$-norcorrole (Figure 1.4.19c). ${ }^{[193]}$ In stark contrast to nanoscopic space composed of aromatic building blocks which shows shielding effect in NMR, the unique inner space surrounded with the antiaromatic building blocks displayed an antiaromatic deshielding effect. ${ }^{[194]}$ Guest compounds incarcerated within 95 show uncommon downfield shifts of up to +14.9 ppm in ${ }^{1} \mathrm{H}$ NMR relative to the free guest.

## 2 Scope of this thesis

Previous examples of fullerene-binders inspired us for rational molecular designs for construction of fullerene-binders with certain properties and functions. Among those fullerene-binders, coordination cages are powerful and versatile hosts which can provide a discrete and isolated space which is suitable to accommodate fullerenes. Until now, many coordination cages which can encapsulate fullerene have been reported as well as their unique behavior in self-assembly and physical properties. As discussed in the General Introduction, $\mathrm{C}_{60}$ is known to show intriguing physical and chemical properties under "Nano-confinement" \& "Hierarchical Assembly". In light of these perspectives, I have chosen to investigate physical and chemical properties of $\mathrm{C}_{60}(\mathrm{~s})$ inside coordination cages based on the established design and concept by our group as a main subject of this dissertation. In this Ph.D. dissertation, the following is described:

C60 in
"Nano-confinement"

- Generation and stabilization of $\mathrm{C}_{60}$ radical anion inside a cationic triptycene-based coordination cage
- Encapsulation capability of a triptycene-based coordination cage towards $\mathrm{C}_{60}$ derivatives and a curved polyaromatic hydrocarbon
- Synthesis of $\mathrm{C}_{60} \mathrm{Pd}(0)_{\mathrm{n}}(\mathrm{n}=1,2)$ by utilizing a triptycene-based coordination cage as a supramolecular mask

C60 in

## "Hierarchical Assembly"

- Synthesis of a pill-shaped coordination cage encapsulating two $\mathrm{C}_{60}$ molecules and guest-uptake and reaction in between two confined $\mathrm{C}_{60} \mathrm{~S}$

3 Generation and stabilization of $\mathrm{C}_{60}$ radical anion inside a cationic coordination cage

#### Abstract

: The $\mathrm{C}_{60}$ radical anion ( $\mathrm{C}_{60}{ }^{\circ-}$ ) is a component of fullerides, which is a superconductive material at a relatively high temperature. Further, $\mathrm{C}_{60}{ }^{\circ-}$ and further reduced species are supposed to be the actual electron transporters in organic photovoltaics containing $\mathrm{C}_{60}$. Thus, $\mathrm{C}_{60^{\circ}}$ is an intriguing radical species to be investigated to further gain insights for material development. However, $\mathrm{C}_{60}{ }^{\circ}$ is a rather unstable species, and thus, a special set up is required to investigate $\mathrm{C}_{60}{ }^{\circ-}$. In this chapter, the synthesis of a triptycene-based ligand and its behavior in self-assembly with $\mathrm{Pd}(\mathrm{II})$ to a Pd2L4 cage is described. The self-assembled cage has a cavity suitable to accommodate a single C60 molecule. Selective one electron reduction of the confined $\mathrm{C}_{60}$ was performed yielding $\mathrm{C}_{60}{ }^{\circ}$ inside the cavity characterized by ESI MS, EPR, and UV-Vis NIR spectroscopy. The generated $\mathrm{C}_{60}{ }^{-}$- inside the cage was found to have a long lifetime up to 1 month most likely due to the confinement effect inside the cationic cage via electrostatic interactions and kinetic protection.

### 3.1 Introduction

(a)

Figure 3.1.1 (a) Self-assembly of $L^{P}$ with $P d(I I)$ to form $\mathrm{Pd}_{2} \mathbf{L}^{\mathbf{P}} 4$ (b) CPK model of $\mathbf{L}^{\mathbf{P}}$ (c) MM2 calculated geometry of $\mathbf{L}^{\mathbf{P}}$ in complex with $\mathrm{C}_{60}$

Since the discovery of fullerene $\mathrm{C}_{60}$ by Kroto, Smalley and Curl, ${ }^{[1]}$ the globular-shaped molecule has inspired scientists across a variety of fields to investigate its physical properties, host-guest ability towards single molecule, ${ }^{[2-4]}$ derivatization, ${ }^{[5,6]}$ material development and so forth. ${ }^{[7]}$ Especially, $\mathrm{C}_{60}$ and its derivatives have been widely utilized in organic devices as an electron-accepting/-transporting material. ${ }^{[8]}$ In such organic devices, one-electron transfer from the donor occurs and the reduced species, $\mathrm{C}_{60}$ radical anion ( $\mathrm{C}_{60}{ }^{\circ-}$ ) and further reduced species are generated. The generated radical species are the actual electron-transporters in the devices and play a key role to harvest charges efficiently. In addition, $\mathrm{C} 60^{\circ-}$ has absorption bands in the NIR region, which provides potential for applications in bioimaging and photodynamic therapy. ${ }^{[9]}$ However, naked $\mathrm{C}_{60}{ }^{-}$has a rather short lifetime in general, especially at ambient temperatures and in solution. ${ }^{[10]}$ Therefore, spectroscopic techniques after bulkelectrolysis conditions or electron donation from a chemical reductant pool are often required for investigating naked $\mathrm{C}_{60} 0^{\circ} \cdot{ }^{[11-15]} \mathrm{Hence}$, the development of a facile method to stabilize generated $\mathrm{C}_{60^{\circ}}$ species in solution is meaningful. As introduced in General

Introduction, coordination-driven self-assembly is a versatile method to construct nanoscopic molecular entities. ${ }^{[16]}$ One of the most important features of coordination cages is their inner space which offers a unique reaction field, ${ }^{[17,18]}$ structural recognition ability, ${ }^{[19,20]}$ stabilization of reactive species ${ }^{[21,22]}$ and so forth. ${ }^{[23]}$ Encapsulation of a specific molecule, i.e. $\mathrm{C}_{60}$, is possible by a rational molecular design as introduced in General Introduction. Further, in many cases, coordination cages possess a charge owing to the metal ions connecting the organic ligands. ${ }^{[24]}$ This electronic property enhances encapsulation of charged species via electrostatic interactions.

Confined $\mathrm{C}_{60}$ inside some cationic coordination cages tends to show a positive shift of the first reduction potential of the encapsulated $\mathrm{C}_{60}{ }^{[25,26]}$ compared to pristine $\mathrm{C}_{60}{ }^{[27]}$ Therefore, electronic interactions between cationic coordination cages and encapsulated $\mathrm{C}_{60^{-}}$can be anticipated. According to those facts, triptycene-based organic ligand $\mathbf{L}^{\mathbf{P}}$ for construction of a coordination cage enabling efficient $\mathrm{C}_{60}$ encapsulation was synthesized (Figure 3.1.1a). In addition, generation of $\mathrm{C}_{60}{ }^{\circ}$ within the formed cationic coordination cage via self-assembly of the synthesized ligand and $\mathrm{Pd}(\mathrm{II})$ has been investigated. Our approaches to construct a coordination cage for $\mathrm{C}_{60}$ encapsulation is based on geometrical matching. Dr. Bin Chen, a former Ph.D. student of our group, has synthesized organic ligands having a curved $\pi$-surface. ${ }^{[28-30]}$ Despite of the rather small surface area, a coordination cage consisted of the curved ligands and $\mathrm{Pd}(\mathrm{II})$ shows quantitative encapsulation of $\mathrm{C}_{60}$ within its cavity most likely via convex-concave interactions. Based on this report, a similar, yet, new ligand having triptycene-backbone has been synthesized aiming for $\mathrm{C}_{60}$ encapsulation. Triptycene is known for attractive interactions with $\mathrm{C}_{60}$ due to the geometrical matching (Figure 3.1.1b and $\mathbf{c}$ ). ${ }^{[31]}$

### 3.2 Results and discussion

Figure 3.2.1 (a) Synthesis of $\mathrm{Pd}_{2} \mathrm{LP}_{4}$ and encapsulation of $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{LP}_{4}$ (b) ${ }^{1} \mathrm{H}$ NMR spectrum of $L^{P}\left(\mathrm{CD}_{3} \mathrm{CN}, 500 \mathrm{MHz}, 298 \mathrm{~K}\right)$ (c) $\mathrm{Pd}_{2} \mathrm{~L}_{4}\left(\mathrm{CD}_{3} \mathrm{CN}, 0.70 \mathrm{mM}, 500 \mathrm{MHz}\right.$, 298 K ) and (d) $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{LP}_{4}\left(\mathrm{CD}_{3} \mathrm{CN}, 0.70 \mathrm{mM}, 500 \mathrm{MHz}, 298 \mathrm{~K}\right)$

Synthesis of $L^{P}$ has been conducted following the literature. ${ }^{[32]}$ The dianhydride precursor was synthesized via 4 steps from o-dichlorobenzene. The condensation reaction to synthesize the desired ligand was performed under a neat condition. After mixing $\mathrm{L}^{\mathrm{P}}$ and 0.5 equiv. of $\left[\mathrm{Pd}(\mathrm{MeCN})_{4}\right]\left(\mathrm{BF}_{4}\right)_{2}$ at $70^{\circ} \mathrm{C}$ for 24 h , quantitative formation of $\mathrm{Pd}_{2} \mathrm{~L}_{4}$ took place (Figure 3.2.1a and $\mathbf{c}$ ). Similar to other Pd(II)-coordination cages, downfield shifts of the pyridine-coordination sites were observed (Figure 3.2.1b and c). ${ }^{[33,34]}$ The formation of $\mathrm{Pd}_{2} \mathrm{~L}_{4}$ was further confirmed by ESI MS, and DOSY (Figure
3.4.10 and Figure 3.4.12). The VOIDOO calculations suggested a sufficient size of the cavity for single $\mathrm{C}_{60}$ encapsulation (Figure 3.4.25). Thus, incarceration of $\mathrm{C}_{60}$ inside the coordination cage was performed by stirring solid $\mathrm{C}_{60}$ in an acetonitrile solution of $\mathrm{Pd}_{2} \mathrm{~L}^{\mathbf{P}}$. After filtration of the remaining powdered $\mathrm{C}_{60}$, a purple solution was obtained, which is a characteristic color of $\mathrm{C}_{60}$.

Figure 3.2.2 $X$-ray structure of (a) $\mathrm{Pd}_{2} \mathrm{~L}_{4}$ and (b) $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{~L}^{\mathrm{P}}$; color legend: gray, blue, red, orange, skyblue for $\mathrm{C}, \mathrm{N}, \mathrm{O}, \mathrm{Pd}$, and $\mathrm{C}_{60}$ respectively

A ${ }^{1} \mathrm{H}$ NMR spectrum was measured for the purple filtrate. In the ${ }^{1} \mathrm{H}$ NMR spectrum, an upfield shift of the protons $\mathrm{H}^{\mathrm{a}}$ which are supposed to be pointing inward the cavity was observed (Figure 3.2.1d), which is in line with the previous study. ${ }^{[28-30]}$ This upfield shift is most likely due to interactions between the protons and the encapsulated $\mathrm{C}_{60}$. The encapsulation was further supported by ESI MS analysis (Figure 3.4.19). The solid-state structure of $\mathrm{Pd}_{2} \mathrm{~L}_{4}$ and $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{~L}_{4}$ was unambiguously elucidated by single crystal X -ray structural analysis (Figure 3.2.2). Plate-like crystals of $\mathrm{Pd}_{2} \mathrm{~L}_{4}$ suitable for crystallographic analysis were obtained by slow vapor diffusion of diisopropylether into an acetonitrile solution of the cage. Single crystals of $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{~L}_{4}$ were grown by slow vapor diffusion of benzene into an acetonitrile solution of $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{~L}^{\mathrm{P}}$. In comparison to $\mathrm{Pd}_{2} \mathrm{~L}^{\mathrm{P}}$, shrinkage of the $\mathrm{Pd} \cdots \mathrm{Cd}$ was observed in the structure of $\mathrm{C}_{6} @ \mathrm{Pd}_{2} \mathrm{~L}_{4}$ by $0.435(9) \AA$, probably to enlarge $\pi-\pi$ interactions between the cage and the confined $\mathrm{C}_{60}$ (Figure 3.4.20 and Figure 3.4.21).
Next, the electron-deficient character of the cage together with the cationic charge originated from the $\mathrm{Pd}(\mathrm{II})$ centers stimulated me to investigate the electronic properties of the encapsulated $\mathrm{C}_{60}$. In general, pristine $\mathrm{C}_{60}$ shows a first reduction potential around ca. -1.0 V in various organic solvents versus $\mathrm{Fc} / \mathrm{Fc}^{+} \cdot{ }^{[27]} \mathrm{A}$ cyclic voltammogram of $\mathrm{Pd}_{2} \mathrm{~L}^{\mathrm{P}} 4$ showcased a first reduction wave at -1.78 V against the $\mathrm{Fc} / \mathrm{Fc}^{+}$reference, which should belong to reduction of the ligands (Figure 3.2.3a). Meanwhile, the cyclic voltammogram of $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{~L}_{4}$ showed irreversible

Figure 3.2.3 Cyclic voltammograms of (a) $\mathrm{Pd}_{2} \mathrm{~L}^{\mathrm{P}_{4}}$ (b) $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{~L}^{\mathrm{P}_{4}}$ (c) and only the first reduction wave of $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{~L}_{4}$ with oxidation wave of $\mathrm{Fc} / \mathrm{Fc}^{+}$; scan rate: $100 \mathrm{mV} / \mathrm{s}$, electrolyte: TBAPF6 in acetonitrile
reduction waves at more cathodic potentials in addition to the quasi-reversible cage reduction at -1.79 V (vs. Fc/Fc+; Figure 3.2.3b). These newly observed waves should be assignable to progressive reduction steps of the encapsulated $\mathrm{C}_{60}$ molecule. DFT calculations implied that the LUMO should be localized on the encapsulated $\mathrm{C}_{60}$ molecule inside the cavity, supporting those observations (Figure 3.2.3d). The first reduction potential for the encapsulated $\mathrm{C}_{60}$ molecule appeared at -0.48 V vs $\mathrm{Fc} / \mathrm{Fc}^{+}$ as a reversible wave when the measurement was performed in a narrower range (Figure 3.2.3c). Note, this value is the most cathodic for $\mathrm{C}_{60}$ encapsulated in coordination cages reported so far. ${ }^{[25,26]}$ This result implies interactions between the reduced anionic species $\mathrm{C}_{60^{\circ}}$ and the cationic cage. DFT calculations in the gasphase further indicate the possible stronger interactions between the cage and $\mathrm{C}_{60}{ }^{\circ}$ than $\mathrm{C}_{60}$ (Table 3.4.6.1).

Figure 3.2.4 ${ }^{1} \mathrm{H}$ NMR spectrum of $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{~L}_{4}$ in the presence of $\mathrm{BNAH}\left(\mathrm{CD}_{3} \mathrm{CN}, 500\right.$ $\mathrm{MHz}, 298 \mathrm{~K})(\mathrm{b}) \mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{~L}_{4} 5$ mins after irradiation with the white LED light source with BNAH (CD3 ${ }_{3} \mathrm{CN}, 500 \mathrm{MHz}, 298 \mathrm{~K}$ ) (c) 2 h after irradiation showing regeneration of original $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{LP}_{4}\left(\mathrm{CD}_{3} \mathrm{CN}, 500 \mathrm{MHz}, 298 \mathrm{~K}\right)$

Encouraged by these results, the generation of $\mathrm{C}_{60}{ }^{\circ}$ inside the coordination cage was investigated. Amongst several possible reductants, 1-benzyl-1,4-dihydronicotinamide (BNAH) has been chosen for this study due to the controllability of one-electron reduction by light irradiation (Figure 3.2.4). Fukuzumi and co-workers have reported one-electron reduction of $\mathrm{C}_{60}$ using BNAH as a reductant. ${ }^{[35]}$ In the reaction mechanism they proposed, energy transfer from $\mathrm{C}_{60}$ in triplet excited states to BNAH triggers this chemical reduction process. From one BNAH, two molecular $\mathrm{C}_{60}$ should be reduced in theory. Therefore, 0.5 equiv. of BNAH was added into $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{~L}_{4}$ in acetonitrile and irradiated with a white LED source. As a result, the ${ }^{1} \mathrm{H}$ NMR signals became broadened which is implying encapsulation of paramagnetic species (Figure 3.2.4b). ${ }^{[36]}$ The broadened signals became sharper over time (Figure 3.2.4c), suggesting deactivation of the encapsulated radical species. In the ESI MS spectrum

Figure 3.2.5 ESI MS spectrum of $\mathrm{C}_{60}{ }^{\circ} @ \mathrm{Pd}_{2} \mathrm{~L}^{\mathrm{P}} 4$ (positive mode)
measured immediately after the photochemical reduction, a prominent signal assignable to $\left[\mathrm{C}_{60} 0^{\circ} @ \mathrm{Pd}_{2} \mathrm{~L}_{4}\right]^{3+}$ was observed (Figure 3.2.5). In addition, a UV-vis-NIR spectrum was measured right after photochemical reduction process. In the absorption spectrum, new absorption bands at 975 and 1111 nm were observed whilst the encapsulated $\mathrm{C}_{60}$ showed absorption at 546 and 599 nm (Figure 3.2.6a-b). The absorption bands in the NIR region are in good accordance with the absorption spectrum of $\mathrm{C}_{60}{ }^{\circ-}$ reported before, further evidencing generation of $\mathrm{C} 60^{--}$inside the cage. ${ }^{[11]}$ Among the observed NIR absorptions, the absorption band at the longer wavelength showed a red-shift by approximately 20-30 nm compared to the reported absorption band of naked $\mathrm{C}_{60^{\circ-}}$ (cf. 1080 nm vs. 1111 nm ). On the other hand, the shorter absorption wavelength is comparable to previous reports. It is reported that the NIR absorptions are originated from an electron transition from SOMO to an unoccupied orbital. ${ }^{[37]}$ Based on resonance Raman spectroscopy studies, two symmetric $A_{g}$ vibrational modes cause the observed splitting. ${ }^{[37]}$ The vibrational mode with higher wavenumber is a so-called "pentagonal-pitch" mode and the other mode is a so called "breathing" mode. Hence, perturbation of the breathing mode is presumed as a potential reason for the bathochromic shift observed in the absorption spectrum, most likely due to the confinement of the radical anion within the cavity of the cationic cage $\mathrm{Pd}_{2} \mathrm{LP}_{4}$.

Control experiments using the empty host showed that the photochemical reduction does not occur (Figure 3.4.36). Further, when the mixture of $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{~L}_{4}$ and $\mathrm{Pd}_{2} \mathrm{~L}_{4}$ was applied to the photochemical reduction, only $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{~L}^{\mathbf{P}} 4$ gave broadened ${ }^{1} \mathrm{H}$

NMR signals (Figure 3.4.35). These results strongly support the generation of $\mathrm{C}_{60}{ }^{\circ}$ within the cage.
The decay of generated $\mathrm{C}_{60^{\circ}}$ inside the cage was investigated by EPR, in collaboration by Shari Meichsner in the Kasanmaschef group, and UV-Vis NIR absorption studies (Figure 3.2.6). The decay of the absorption intensity in the NIR region was observed over time due to deactivation of generated $\mathrm{C}_{60}{ }^{\circ}$ (Figure 3.2.6a). The half-lifetime of $\mathrm{C}_{60}{ }^{\circ}$ inside the cage was estimated to be 13 mins from the decay of the 1111 nm absorption band in acetonitrile at 295 K under ambient conditions. Generated $\mathrm{C}_{60^{-}}$within the coordination cage can be chemically oxidized back to original $\mathrm{C}_{60}$ by tetracyanoethylene (TCNE). The absorbance in the NIR region instantly vanished after addition of TCNE and gave the almost identical absorption spectrum to $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{~L}_{4}$ after 1 h (Figure 3.4.43). The clean oxidation process was further investigated by an ${ }^{1} \mathrm{H}$ NMR study as well (Figure 3.4.44). This reduction-oxidation process suggests a potential use of the host-guest complex for photoredox catalysis.

Figure 3.2.6 UV-Vis NIR absorption spectrum (acetonitrile, 0.35 mM , 295 K ) of (a) $\mathrm{C}_{60} 0^{\circ} @ \mathrm{Pd}_{2} \mathrm{P}_{4}$ in the air (b) $\mathrm{C}_{60}{ }^{\circ} @ \mathrm{Pd}_{2} \mathrm{~L}_{4}$ prepared inert condition; EPR spectra of (c) $\mathrm{C}_{60} 0^{-} @ \mathrm{Pd}_{2} \mathrm{~L}_{4}$ in the air and (d) $\mathrm{C}_{60}{ }^{\circ}$ @Pd $\mathrm{L}^{\mathrm{P}_{4}}$ prepared under inert condition; both EPR spectra were measured at X -band at 100 K . The corresponding simulations are shown in the inset as red line. The figure is reproduced from the data published ${ }^{[51]}$

The lifetime of $\mathrm{C}_{60}{ }^{-}$inside $\mathrm{Pd}_{2} \mathrm{~L}^{\mathrm{P}} 4$ was further investigated in inert atmosphere (Figure 3.2.6b). Absorption bands with higher intensity were observed at the same wavelength in the NIR region but their decline was found to be dramatically elongated by removing oxygen, a potential oxidant in the system. ${ }^{[10]}$ In addition, X-band EPR spectra were measured for $\mathrm{C}_{60} 0^{-} @ \mathrm{Pd}_{2} \mathrm{~L}_{4}$ prepared in air or inert condition at 100 K (Figure 3.2.6cd). For the measurement under inert condition, the sample was prepared in the glovebox filled with $\mathrm{N}_{2}$. The EPR signal originating from $\mathrm{C}_{60}{ }^{\circ}$, having a $g$ value of 1.999, was observed in both samples (3.4.8 for details). ${ }^{[12]}$ On the other hand, an additional signal with $g_{i s o}=2.001$ assignable to an oxygenated species was observed in the case of the sample prepared in air (Figure 3.2.6c). ${ }^{[38]}$ The presence of such an oxygenated species was also evidenced by ESI-MS analysis (Figure 3.4.33). Contrary, encapsulated $\mathrm{C}_{60^{\circ-}}$ was the only paramagnetic species observed in the sample prepared under inert atmosphere (Figure 3.4.45). The half-lifetime of $\mathrm{C}_{60}{ }^{\circ-}$ was estimated to be 14 min under aerobic conditions by these EPR studies, while the comparable value obtained by the UV-Vis NIR absorption (13 min). Meanwhile, the EPR investigations of the sample prepared under inert condition showed a half-lifetime of 893 min , while a half-lifetime of about 300 min was estimated by UV-Vis NIR spectroscopy-based analysis (3.4.8.3). A potential reason for the large distribution would be how the samples were handled for the absorption and EPR studies. Both samples were prepared in the glovebox. While the samples could be stored in the glovebox for the aliquot-based EPR studies until the measurement time, the sample for the absorption study was let stand outside the glovebox once the measurement has started. Therefore, it can be assumed that more contamination of oxygen occurred for the sample used for the absorption study. It should be noted that the sample prepared under inert atmosphere showed the EPR signal even after one month, which clearly showing a stabilization of $\mathrm{C}_{60}{ }^{--}$by nano-confinement inside the coordination cage. ${ }^{[12,52]}$ Nano-confinement inside the coordination cage provides the electrostatic interactions between $\mathrm{C}_{60^{-}}$and the cationic cage as well as protection of the encapsulated $\mathrm{C} 60^{\circ}$ preventing access of oxidants.

### 3.3 Conclusion

In conclusion, the synthesis of the triptycene-based coordination cage and its accommodation capability towards $\mathrm{C}_{60}$ has been investigated. Owing to the molecular
design, taking advantage of convex-concave interactions between the curved $\pi$ surface of the ligand and $\mathrm{C}_{60}$, encapsulation of $\mathrm{C}_{60}$ proceeds quantitatively. The formation of the empty host and the host-guest complex was fully characterized by NMR, ESI MS, and their structures in the solid-state were revealed by single crystal X-ray structure analysis. The photochemical reduction using BNAH was performed to generate $\mathrm{C}_{60^{-}}$inside the coordination cage. Generation of $\mathrm{C}_{60^{\circ}}$ has been characterized by NMR, ESI MS, UV-Vis NIR, and EPR spectroscopy. To my surprise, generated $\mathrm{C} 60^{\circ}$ has a long lifetime of utmost 1 month under inert atmosphere. The stabilization effect is probably due to confinement effects within the cationic coordination cage via electrostatic interactions between the anionic guest and the cationic host as well as steric protection provided by the cage hampering access of oxidants.

### 3.4 Appendix

### 3.4.1 Material and method

Unless otherwise stated, all chemicals were purchased from commercial sources and used as received. $\left[\mathrm{Pd}(\mathrm{MeCN})_{4}\right]\left(\mathrm{BF}_{4}\right)_{2}$ and 3 -aminopyridine were purchased from Sigma-Aldrich. Precursors to ligand $L^{\mathbf{P}}$ were prepared according to literature procedures. ${ }^{[30,32]}$ Electrospray ionization (ESI) mass spectra were recorded using Bruker ESI-timsTOF and compact mass spectrometers using Agilent tune mix as calibrant. NMR experiments were performed using Bruker AV 500 Avance NEO FT NMR and Bruker Avance III HD 700 MHz spectrometers. EPR experiments were performed using a Bruker EMX-Nano Benchtop spectrometer equipped with a continuous-flow nitrogen cryostat. 1H and 13C signals were referenced to the residual solvent peak: acetonitrile ( $1.94 \mathrm{ppm}, 118.26 \mathrm{ppm}$ ). DFT calculations were performed using Gaussian Gaussian 16, Revision B.01. ${ }^{[39]}$ Hydrodynamic radii of compounds were calculated from the Stokes-Einstein equation (eq 1) where $D$ is a diffusion coefficient, $k_{B}$ is Boltzman constant, $T$ is a temperature, $\eta$ is a viscosity of the solvent, and $r_{\mathrm{H}}$ is a hydrodynamic radius of interest.

$$
D=\frac{k_{B} T}{6 \pi n r_{H}}(\text { eq } 1)
$$

### 3.4.2 Synthesis of $L^{P}$

Figure 3.4.1 Synthesis of $L^{P}$

Triptycene-2,3,6,7-tetracarboxylic dianhydride ( $39.2 \mathrm{mg}, 0.1 \mathrm{mmol}$ ) and 3aminopyridine ( $282.2 \mathrm{mg}, 3.0 \mathrm{mmol}$ ) were placed in a 10 mL vial and Ar gas was purged into the vial. The sealed vial was heated at $180^{\circ} \mathrm{C}$ for 30 min while stirring and the resulting mixture was cooled to ambient temperature. The crude material was purified by silica-gel column chromatography $\left(\mathrm{CHCl}_{3} / \mathrm{MeOH}=50: 1\right)$. After evaporating organic solvents, the obtained compound was dissolved in 1.0 mL of $\mathrm{CHCl}_{3}$ and precipitated by addition of $\mathrm{Et}_{2} \mathrm{O}(5 \mathrm{~mL})$. After filtration, desired compound 1 was obtained as a pale-yellow powder in quantitative yield. ( $54.6 \mathrm{mg}, 100 \%$ )
${ }^{1} \mathrm{H}$ NMR ( $500 \mathrm{MHz}, \mathrm{CD}_{3} \mathrm{CN}, 298 \mathrm{~K}$ ): $\delta(\mathrm{ppm}) \mathbf{a} 8.61(\mathrm{~d}, J=2.5,2 \mathrm{H})$, b 8.56 (dd, $J=$ $1.6,5.5 \mathrm{~Hz}, 2 \mathrm{H}$ ), e $8.04(\mathrm{~s}, 4 \mathrm{H})$, d 7.78 (ddd, $J=8.5,2.5,1.6 \mathrm{~Hz}, 2 \mathrm{H})$, f 7.59 (dd, $J=$ $5.5,3.3 \mathrm{~Hz}, 2 \mathrm{H}$ ), c 7.48 (ddd, $J=8.5,5.5,0.7 \mathrm{~Hz}, 2 \mathrm{H}$ ), g 7.14 (dd, $J=5.5,3.3 \mathrm{~Hz}, 2 \mathrm{H}$ ), h 6.16 (s, 2H)
${ }^{13} \mathrm{C}$ NMR ( $175 \mathrm{MHz}, \mathrm{CD}_{3} \mathrm{CN}, 298 \mathrm{~K}$ ): $\delta(\mathrm{ppm}) 167.76,152.52,149.78,148.55,143.57$, $135.05,131.24,130.02,127.36,125.81,124.68,120.31,54.73$
While 13 signals must be observed in theory, 13 signals were found.

### 3.4.5 Single crystal X-ray structure analysis

### 3.4.5.1 X-ray Crystallography

$\mathrm{Pd}_{2} \mathrm{~L}_{4}$ and $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{~L}_{4}$ were studied using single-crystal X -ray diffraction. Due to very thin plate or needle-shaped crystals, the analysis was hampered by the limited scattering power of the samples not allowing to reach the desired (sub-)atomic resolution using our modern in-house micro-focused X-ray Cu-K ${ }_{\alpha}$ source. Gaining detailed structural insight thus required cryogenic crystal handling and highly brilliant synchrotron radiation. Hence, diffraction data of both of supramolecular assemblies was collected during two beamtime shifts at macromolecular synchrotron beamline P11, PETRA III, DESY. ${ }^{[40]}$ Counterion and solvent flexibility required carefully adapted macromolecular refinement protocols employing geometrical restraint dictionaries, similarity restraints and restraints for anisotropic displacement parameters (ADPs). The crystal structures were refined and deposited on the CCDC database by Dr. Julian J. Holstein. In addition, the following detail description of the refinement was contributed by Dr. Julian J. Holstein.

### 3.4.5.2 $\mathrm{Pd}_{2} \mathrm{LP}_{4}$

Figure 3.4.20 X-ray structure of $\mathrm{Pd}_{2} \mathrm{~L}^{\mathrm{P}}$ 4. Hydrogen atoms, counter anions, solvent molecules are omitted for clarity. Color scheme: C (gray), N (blue), O (red), and Pd (orange)

Single crystals were grown by slow diffusion of diisopropyl ether into a solution of $\mathrm{Pd}_{2} \mathrm{~L}_{4}$ in acetonitrile. A single crystal of $\mathrm{Pd}_{2} \mathrm{~L}_{4}$ in mother liquor was pipetted onto a glass slide containing NVH oil. To avoid cracking of the crystal, the crystal was quickly mounted onto a 0.04 mm nylon loop and immediately flash cooled in liquid nitrogen. Crystals were stored at cryogenic temperature in dry shippers, in which they were safely transported to macromolecular beamline P11 at Petra III, ${ }^{[40]}$ DESY, Germany. A wavelength of $\lambda=0.6888 \AA$ was chosen using a liquid $N_{2}$ cooled double crystal monochromator. Single crystal X-ray diffraction data was collected at 80(2) K on a single axis goniometer, equipped with an Oxford Cryostream 800 open flow cooling device and a Pilatus 6M fast detector. 3600 diffraction images were collected in a $360^{\circ}$ $\varphi$ sweep at a detector distance of $170 \mathrm{~mm}, 100 \%$ filter transmission, $0.1^{\circ}$ step width and 0.1 seconds exposure time per image. Data integration and reduction were undertaken using XDS. ${ }^{[41]}$ The structure was solved by intrinsic phasing/direct methods using SHELXT ${ }^{[42]}$ and refined with SHELXL ${ }^{[43]}$ using 22 CPU cores for fullmatrix least-squares routines on $F^{2}$ and ShelXIe ${ }^{[44]}$ as a graphical user interface and the DSR program plugin was employed for modeling. ${ }^{[45,46]}$ The asymmetric unit contains half a cage. One of the two co-crystallized tetrafluoroborate anions was modelled with two discrete positions refining their occupancy factor to 56:44 using a free variable. Despite reaching $0.8 \AA$ resolution, disorder and poor crystal quality
required stereochemical restraints to be employed for ensuring a sensible geometry of the organic part of the structure.
Stereochemical restraints for the ligands $L^{\mathbf{P}}$ (residue class TRP) and co-crystallized diisolpropylether solvent molecule (residue class DIP) were generated by the GRADE program using the GRADE Web Server (http://grade.globalphasing.org) and applied in the refinement. A GRADE dictionary for SHELXL contains target values and standard deviations for 1,2-distances (DFIX) and 1,3-distances (DANG), as well as restraints for planar groups (FLAT). All displacements for non-hydrogen atoms were refined anisotropically. The refinement of ADPs for carbon, nitrogen and oxygen atoms was enabled by a combination of similarity restraints (SIMU) and rigid bond restraints (RIGU). ${ }^{[47]}$ The contribution of the electron density from disordered counterions and solvent molecules, which could not be modeled with discrete atomic positions, were handled using the SQUEEZE ${ }^{[48]}$ routine in PLATON. ${ }^{[49]}$ The solvent mask file (.fab) computed by PLATON were included in the SHELXL refinement via the ABIN instruction leaving the measured intensities untouched.

### 3.4.5.3 $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{~L}^{\mathrm{P}} 4$

Figure 3.4.21 X-ray structure of $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{~L}_{4}$. Hydrogen atoms, counter anions, solvent molecules are omitted for clarity. Color scheme: C (gray), N (blue), O (red), Pd (orange), C60 (light blue)

Single crystals were grown by slow diffusion of benzene into a solution of $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{~L}^{\mathbf{P}} \mathbf{4}^{2}$ in acetonitrile. A single crystal of $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{~L}_{4}$ in mother liquor was pipetted onto a glass slide containing NVH oil. To avoid cracking of the crystal, the crystal was quickly mounted onto a 0.2 mm nylon loop and immediately flash cooled in liquid nitrogen.

Crystals were stored at cryogenic temperature in dry shippers, in which they were safely transported to macromolecular beamline P11 at Petra III ${ }^{[3]}$, DESY, Germany. A wavelength of $\lambda=0.6888 \AA$ was chosen using a liquid $N_{2}$ cooled double crystal monochromator. Single crystal X-ray diffraction data was collected at 80(2) K on a single axis goniometer, equipped with an Oxford Cryostream 800 open flow cooling device and a Pilatus 6M fast detector. 3600 diffraction images were collected in a $360^{\circ}$ $\varphi$ sweep at a detector distance of $170 \mathrm{~mm}, 100 \%$ filter transmission, $0.1^{\circ}$ step width and 0.1 seconds exposure time per image. Data integration and reduction were undertaken using XDS. ${ }^{[40]}$ The structure was solved by intrinsic phasing/direct methods using SHELXT ${ }^{[41]}$ and refined with SHELXL ${ }^{[42]}$ using 22 CPU cores for fullmatrix least-squares routines on $F^{2}$ and ShelXIe ${ }^{[43]}$ as a graphical user interface and the DSR program plugin was employed for modeling. ${ }^{[44,45]}$

The asymmetric unit contains one full cage with $\mathrm{C}_{60}$ encapsulated. Three of seven cocrystallized benzene solvent molecules were modelled with two discrete positions refining their occupancy factor for two of which to 67:33 and 42:58 for the other using a free variable. One of the four co-crystallized tetrafluoroborates was modelled with two discrete positions refining their occupancy factor to 70:30 using a free variable. Despite reaching $0.7 \AA$ resolution, disorder and poor crystal quality required stereochemical restraints to be employed for ensuring a sensible geometry of the organic part of the structure.

Stereochemical restraints for the ligands 1 (residue class TRP) and co-crystallized benzene solvent molecules (residue class BEN) were generated by the GRADE program using the GRADE Web Server (http://grade.globalphasing.org) and applied in the refinement. A GRADE dictionary for SHELXL contains target values and standard deviations for 1,2-distances (DFIX) and 1,3-distances (DANG), as well as restraints for planar groups (FLAT). All displacements for non-hydrogen atoms were refined anisotropically. The refinement of ADPs for carbon, nitrogen and oxygen atoms was enabled by a combination of similarity restraints (SIMU) and rigid bond restraints (RIGU). ${ }^{[46]}$ The contribution of the electron density from disordered counterions and solvent molecules, which could not be modeled with discrete atomic positions were handled using the SQUEEZE ${ }^{[47]}$ routine in PLATON. ${ }^{[48]}$ The solvent mask file (.fab) computed by PLATON were included in the SHELXL refinement via the ABIN instruction leaving the measured intensities untouched.

### 3.4.6 Electronic properties

### 3.4.6.1 Cyclic voltammetry

Cyclic voltammetry was performed using an Metrohm Autolab PGSTAT101 potentiostat and analyzed by using NOVA software ver. 2.1. All experiments were carried out in 0.1 M acetonitrile solutions of tetrabutylammonium hexafluorophosphate (TBAPF $6,99.9 \%$ purity). To an acetonitrile solution of each cage, an appropriate amount of $\mathrm{TBAPF}_{6}$ was added so that the concentration of $\mathrm{TBAPF}_{6}$ became 0.1 M . The voltammograms were measured using a glassy carbon working electrode, $\mathrm{Ag} / \mathrm{AgNO}_{3}(0.01 \mathrm{M}$ in 0.1 M TBAPF 6 acetonitrile solution) as a reference electrode, and a Pt wire as a counter electrode under $100 \mathrm{mV} / \mathrm{s}$ scan rate under $\mathrm{N}_{2}$ atmosphere.

### 3.4.6.2 Theoretical studies

All calculations were conducted using the Gaussian 16 program. The single point calculation was performed using the optimized geometry to calculate molecular orbitals.

### 3.4.6.2.2

The single point calculations were performed at DFT-M06-2X level of theory using basis-set $6-31 \mathrm{G}(\mathrm{d}, \mathrm{p})$ for H, C, N, O atoms and Lanl2dz as basis-set for Pd atoms considering solvation effects by the Polarizable Continuum Model (PCM). As the input, the optimized geometry calculated at M06-2X/Lanl2dz level of theory was used.

Figure 3.4.23 Geometry of $\left[\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{~L}_{4}\right]^{4+}(\mathrm{MO6-2X} / 6-31 \mathrm{G}(\mathrm{d}, \mathrm{p})$ for H, C, N, O atoms and Lanl2dz for Pd atoms) and visualization of the LUMO

### 3.4.6.2.3 $\mathrm{Pd}_{2} \mathrm{~L}_{4}$

Figure 3.4.24 Gas-phase optimized geometry of $\left[\mathrm{Pd}_{2} \mathrm{~L}_{4}\right]^{4+}$ (M06-2X/Lanl2dz)

### 3.4.6.2.4 VOIDOO calculations

The size of inner cavity was calculated with VOIDOO using the optimized geometry for $\mathrm{Pd}_{2} \mathrm{~L}^{\mathrm{P}_{4}}$ calculated at M06-2X/Lanl2dz using a primary grid and plot grid spacing of $0.1 \AA$ and 10 cycles of volume refinement with the probe size radius of $3.0 \AA$, the minimum radius such that it would not exit the cavity of the structures. Molecular visualization was done using Pymol. ${ }^{[15]}$

Figure 3.4.25 Calculated void space as shown (blue mesh) within $\mathrm{Pd}_{2} \mathrm{LP}_{4}\left(651 \AA^{3}\right)$. Color scheme: C, dark gray; N, blue; O, red; Pd, orange.

### 3.4.6.2.5 $\mathrm{C}_{60}{ }^{\circ}$ @ $\mathrm{Pd}_{2} \mathrm{LP}_{4}$

At first, geometry optimization was performed at UB3LYP/Lanl2dz level of theory. Subsequently, a single point calculation was performed with SCRF (PCM=acetonitrile) at UB3LYP/6-31G(d,p) for $\mathrm{H}, \mathrm{C}, \mathrm{N}, \mathrm{O}$ atoms and Lanl2dz for Pd atom.

Figure 3.4.26 The gas-phase optimized geometry of $\left[\mathrm{C}_{60}{ }^{-} @ \mathrm{Pd}_{2} \mathrm{~L}_{4}\right]^{3+}$ (UB3LYP/Lanl2dz)

Figure 3.4.27 SOMO and LUMO of $\left[\mathrm{C}_{60}{ }^{-} @ \mathrm{Pd}_{2} \mathrm{~L}^{\mathrm{P}}\right]^{3+}$ (UB3LYP/6-31G(d,p) for $\mathrm{H}, \mathrm{C}$, $\mathrm{N}, \mathrm{O}$ atoms and Lanl2dz for Pd atom)

### 3.4.6.2.6 DFT-computed energies of host-guest complex formation with $\mathrm{C}_{60}$ and $\mathrm{C}_{60}{ }^{-}$

To gain information on the stabilization effect of $\mathrm{C}_{60^{-}}$inside the cage, DFT calculations were performed to estimate the energy changes by comparing the total electron energy difference for host-guest complex formation with $\mathrm{C}_{60}$ and $\mathrm{C}_{60}{ }^{\circ}$. First, the geometries of the host-guest complexes were optimized at B3LYP/Lanl2dz level. Then, each geometry of the guest and the host were extracted and single point calculations were conducted at B3LYP level of theory using basis-set $6-31 \mathrm{G}(\mathrm{d}, \mathrm{p})$ for H, C, N, O atoms and Lanl2dz as basis-set for Pd atoms for the extracted geometries. As a result, the encapsulation of $\mathrm{C}_{60}{ }^{\circ} @ \mathrm{Pd}_{2} \mathrm{~L}^{\mathrm{P}_{4}}$ was found to be significantly favored over the formation of $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{~L}_{4}$ by $670 \mathrm{~kJ} / \mathrm{mol}$, a value that would certainly be lower in polar solution containing counter anions but still indicates strong interaction between the cationic host and anionic guest.

### 3.4.7 Generation of $\mathrm{C}_{60}{ }^{-}$inside $\mathrm{Pd}_{2} \mathrm{~L}_{4}$

Figure 3.4.29 Photochemical reduction of encapsulated $\mathrm{C}_{60}$ inside $\mathrm{Pd}_{2} \mathrm{~L}_{4}$

To an acetonitrile solution of $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{LP}_{4}(0.70 \mathrm{mM}, 0.60 \mathrm{~mL}, 0.42 \mu \mathrm{~mol})$ 1-benzyl-1,4-dihydronicotinamide (BNAH) in acetonitrile ( $20.0 \mathrm{mM}, 10.5 \mu \mathrm{~L}, 0.21 \mu \mathrm{~mol}$ ) was added in the dark. The solution was irradiated with a white LED light source for 2 min after which the described measurements were carried out. For samples in inert atmosphere: the samples were handled and transferred to closed tubes/cuvettes for analysis in a glove box filled with $\mathrm{N}_{2}$. To avoid oxygen contamination, the samples were sealed inside the glove box.

ESI MS found 1039.7808; calcd. for $\left[\left(\mathrm{C}_{34} \mathrm{H}_{18} \mathrm{~N}_{4} \mathrm{O}_{4}\right) 4 \mathrm{Pd}_{2} \mathrm{C}_{60}\right]^{3+} 1039.7816$

### 3.4.7.1 ${ }^{1} \mathrm{H}$ NMR spectrum of $\mathrm{C}_{60}{ }^{\circ} @ \mathrm{Pd}_{2} \mathrm{LP}_{4}$

Figure 3.4.30 ${ }^{1} \mathrm{H}$ NMR spectrum of $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{~L}_{4}$ after photochemical reduction

### 3.4.7.2 ESI MS spectrum of $\mathrm{C}_{60}{ }^{\circ} @ \mathrm{Pd}_{2} \mathrm{~L}_{4}$

To an acetonitrile solution of $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{LP}_{4}$, 1-benzyl-1,4-dihydronicotinamide (BNAH) in acetonitrile was added in the dark. The solution was irradiated with a white LED light source for 2 mins and measurements were carried out immediately after irradiation. For the sample in inert atmosphere: the sample were prepared in glove box filled with $\mathrm{N}_{2}$.

## Sample prepared in air:

Figure 3.4.31 ESI-MS spectrum of $\mathrm{C}_{60} 0^{\circ} @ \mathrm{Pd}_{2} \mathrm{~L}_{4}$ prepared under aerobic condition (positive mode)

## Sample prepared in the glovebox:

Figure 3.4.32 ESI-MS spectrum of $\mathrm{C}_{60}{ }^{\circ} @ \mathrm{Pd}_{2} \mathrm{~L}_{4}$ prepared under inert condition (positive mode)

Figure 3.4.33 Comparison of ESI-MS spectra of $\mathrm{C}_{60}{ }^{\circ}$ @ $\mathrm{Pd}_{2} \mathrm{LP}_{4}$ prepared in the air and the glovebox showing clear oxygenation for the sample prepared in the air (positive mode)

### 3.4.7.3 Control experiments

Figure 3.4.34 Photo chemical reduction of $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{~L}_{4}$ in the presence of empty $\mathrm{Pd}_{2} \mathrm{LP}_{4}$

To a mixture of $\mathrm{Pd}_{2} \mathbf{1}_{4}$ and $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{~L}_{4}$ ( 0.35 mM for each complex, 0.60 mL ) 1-benzyl-1,4-dihydronicotinamide (BNAH) in acetonitrile ( $10.5 \mu \mathrm{~L}, 10.0 \mathrm{mM}, 0.1 \mu \mathrm{~mol}$ ) was added in the dark. The solution was irradiated with a white LED light source for 2 mins and then measurements were carried out. As a result, only the fullerene-containing $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{~L}^{\mathrm{P}_{4}}$ host-guest complex gave broadened ${ }^{1} \mathrm{H}$ NMR signals while the signals of empty $\mathrm{Pd}_{2} \mathrm{LP}_{4}$ did not change. This shows that the encapsulated fullerene is not only the photocatalyst but also the recipient of the electron.

Figure 3.4.35 ${ }^{1} \mathrm{H}$ NMR spectra ( $\mathrm{CD}_{3} \mathrm{CN}, 500 \mathrm{MHz}$, 298 K ) showing selective reduction of $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{~L}_{4}$ by photochemical reduction

Figure 3.4.36 Attempted photochemical reduction of $\mathrm{Pd}_{2} \mathrm{~L}_{4}$

To a mixture of $\mathrm{Pd}_{2} \mathrm{LP}_{4}(0.70 \mathrm{mM}, 0.60 \mathrm{~mL})$ 1-benzyl-1,4-dihydronicotinamide (BNAH) in acetonitrile ( $10.5 \mu \mathrm{~L}, 20.0 \mathrm{mM}, 0.2 \mu \mathrm{~mol}$ ) was added in the dark. The solution was irradiated with a white LED light source for 2 mins and then measurements were carried out. However, no photochemical reduction took place.

Figure 3.4.37 ${ }^{1} \mathrm{H}$ NMR spectra $\left(\mathrm{CD}_{3} \mathrm{CN}, 500 \mathrm{MHz}, 298 \mathrm{~K}\right)$ showing that no photochemical reduction occurred

### 3.4.7.4 UV-Vis NIR absorption

To an acetonitrile solution of $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{LP}_{4}(0.35 \mathrm{mM}, 2.00 \mathrm{~mL}, 0.70 \mu \mathrm{~mol})$ 1-benzyl-1,4-dihydronicotinamide (BNAH) in acetonitrile ( $20.0 \mathrm{mM}, 17.5 \mu \mathrm{~L}, 0.3 \mu \mathrm{~mol}$ ) was added in the dark. The solution was irradiated with a white LED light source for 2 min and then measurements were carried out. For samples in inert atmosphere: the samples were prepared in a glove box filled with $\mathrm{N}_{2}$. To avoid oxygen contamination, the samples were sealed in the glove box. After taking out from the glove box, the sample was irradiated with a white LED light source for 2 min and then measurements were carried out. All spectra were measured using an Agilent Cary 5000 double beam UV-vis-NIR spectrometer (175-3300 nm).

### 3.4.7.4.1 UV-Vis-NIR spectrum of $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{~L}^{\mathrm{P}} 4$

Figure 3.4.38 UV-Vis-NIR spectrum of $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{~L}^{\mathbf{P}} 4\left(0.35 \mathrm{mM}, \mathrm{CD}_{3} \mathrm{CN}, 298 \mathrm{~K}, I=1.0\right.$ cm ) in the presence of BNAH in the dark

### 3.4.7.4.2 UV-Vis-NIR spectra of $\mathrm{C}_{60}{ }^{\circ} @ \mathrm{Pd}_{2} \mathrm{~L}^{\mathrm{P}} 4$ under aerobic conditions

Figure 3.4.39 UV-Vis-NIR spectra of $\mathrm{C}_{60} 0^{-} @ \mathrm{Pd}_{2} \mathrm{~L}^{\mathrm{P}_{4}}\left(0.35 \mathrm{mM}, \mathrm{CD}_{3} \mathrm{CN}, 295 \mathrm{~K}, I=1.0\right.$ cm ) under aerobic conditions over time ( $\varepsilon_{1111}=5637 \mathrm{M}^{-1} \mathrm{~cm}^{-1}$, $\varepsilon_{975}=2070 \mathrm{M}^{-1} \mathrm{~cm}^{-1}$ ).

The absorption decay at 1111 nm and 975 nm was analyzed to obtain kinetic parameters for the deactivation of $\mathrm{C}_{60}{ }^{\circ}$. We have attempted to fit the data as pseudo first order (eq. 1) and second order (eq. 2) reaction as shown below. To estimate the concentration of $\mathrm{C}_{60}{ }^{\circ} @ \mathrm{Pd}_{2} \mathbf{1}_{4}$, absorption coefficient $\varepsilon$ was calculated from the absorbance at 0 min measured in $\mathrm{N}_{2}$ atmosphere for each wavelength (4.3.3.). The half lifetime estimated from second order reaction fitting was calculated using $3.5 \times 10^{-}$ ${ }^{4} \mathrm{M}$ was used as [AO]. As a result, the pseudo first order fit for the signal at 1111 nm gave a similar half-lifetime of the radical ( 13 min ) to the one estimated by EPR spectroscopy ( 14 min ) as shown in section 4.6.3.

$$
\begin{aligned}
{[A] } & =\left[A_{0}\right] e^{-k t} \cdots(1) \\
\frac{1}{[A]} & =\frac{1}{\left[A_{0}\right]}+k t \cdots(2)
\end{aligned}
$$

Figure 3.4.40 Absorbance decay of $\mathrm{C}_{60}{ }^{\circ} @ \mathrm{Pd}_{2} \mathrm{LP}_{4}\left(0.35 \mathrm{mM}, \mathrm{CD}_{3} \mathrm{CN}, 295 \mathrm{~K}, I=1.0\right.$ cm ) under aerobic conditions over time (a) absorption change at 1111 nm fitted as pseudo first order reaction (b) as second order reaction (c) absorption change at 975 nm fitted as pseudo first order reaction (d) as second order reaction

Table 3.4.7.1. Summary of reaction rates and half-lifetimes under aerobic conditions obtained by the fittings of the absorption decay at 1111 nm , yielding a pseudo-first order half-lifetime of 13 min which is in good agreement with the EPR-derived result ( 14 min ; see below). Fittings of the signal decay at 975 nm were too poor to result in trustworthy values.

|  | 1111 nm |  |
| :---: | :---: | :---: |
|  | $k$ | $t_{1 / 2}(\mathrm{~min})$ |
| pseudo first order | $5.2 \times 10^{-2}\left(\mathrm{~min}^{-1}\right)$ | 13 |
| second order | $983.3\left(\mathrm{M}^{-1} \mathrm{~min}^{-1}\right)$ | 3 |

3.4.7.4.3 UV-Vis-NIR spectra of $\mathrm{C}_{60}{ }^{\circ} @ \mathrm{Pd}_{2} \mathrm{~L}_{4}$ in inert atmosphere

Figure 3.4.41 UV-Vis-NIR spectra of $\mathrm{C}_{60} 0^{\circ} @ \mathrm{Pd}_{2} \mathrm{~L}^{\mathrm{P}}\left(0.35 \mathrm{mM}, \mathrm{CD}_{3} \mathrm{CN}, 295 \mathrm{~K}, I=1.0\right.$ cm ) in $\mathrm{N}_{2}$ atmosphere over time ( $\left.\varepsilon_{1111}=5637 \mathrm{M}^{-1} \mathrm{~cm}^{-1}, \varepsilon_{975}=2070 \mathrm{M}^{-1} \mathrm{~cm}^{-1}\right)$

Under anaerobic conditions, the absorption decay was again analyzed at 1111 nm and 975 nm to obtain kinetic parameters of the deactivation of $\mathrm{C}_{60}{ }^{\circ}$. We have attempted to fit the data as pseudo first order (eq. 1) and second order reaction (eq. 2) as shown above. Owing to the almost linearly appearing signal decay in the monitored time regime, all fittings gave half-lifetimes with similar magnitude around 300 min, which should therefore be considered as a rough estimate. To estimate the
concentration of $\mathrm{C}_{60}{ }^{\circ} @ \mathrm{Pd}_{2} \mathrm{~L}^{\mathrm{P}} 4$, absorption coefficient $\varepsilon$ was calculated from Absorbance at 0 min for each wavelength. The half lifetime estimated from second order reaction fitting was calculated using $3.5 \times 10^{-4} \mathrm{M}$ was used as [ $\mathrm{A}_{0}$ ].

Figure 3.4.42 Absorbance decay of $\mathrm{C}_{60^{\circ}}-\mathrm{PPd}_{2} \mathrm{LP}_{4}\left(0.35 \mathrm{mM}, \mathrm{CD}_{3} \mathrm{CN}, 295 \mathrm{~K}, I=1.0\right.$ cm ) under $\mathrm{N}_{2}$ atmosphere over time: (a) absorption change at 1111 nm fitted as pseudo first order reaction (b) as second order reaction (c) absorption change at 975 nm fitted as pseudo first order reaction (b) as second order reaction

Table 3.4.7.2 Summary of reaction rates and half-lifetimes under $\mathrm{N}_{2}$ atmosphere obtained by the fittings

|  | 1111 nm |  |  | 975 nm |
| :--- | :--- | :--- | :--- | :--- |
|  | $k$ | $t_{1 / 2}(\mathrm{~min})$ | $k$ | $t_{1 / 2}(\mathrm{~min})$ |
| pseudo first <br> order | $2.6 \times 10^{-3}\left(\mathrm{~min}^{-1}\right)$ | 263 | $2.2 \times 10^{-3}\left(\mathrm{~min}^{-1}\right)$ | 302 |
| second order | $10.0\left(\mathrm{M}^{-1} \mathrm{~min}^{-1}\right)$ | 283 | $8.4\left(\mathrm{M}^{-1} \mathrm{~min}^{-1}\right)$ | 337 |

### 3.4.7.5 Chemical oxidation of $\mathrm{C}_{60}{ }^{\circ} @ \mathrm{Pd}_{2} \mathrm{~L}_{4}$

To an acetonitrile solution of $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{~L}_{4}(0.35 \mathrm{mM}, 1.0 \mathrm{~mL}, 0.4 \mu \mathrm{~mol})$ 1-benzyl-1,4dihydronicotinamide (BNAH) in acetonitrile ( $17.5 \mu \mathrm{~L}, 10.0 \mathrm{mM}, 0.17 \mu \mathrm{~mol}$ ) was added in the dark. The solution was irradiated with a white LED light source for 2 mins and measurements were carried out immediately after irradiation. After measuring the absorption spectrum, tetracyanoethylene (TCNE) in acetonitrile ( $17.5 \mu \mathrm{~L}, 20.0 \mathrm{mM}$, $0.4 \mu \mathrm{~mol})$ was quickly added under $\mathrm{N}_{2}$ flow. Absorption spectra were measured immediately after addition of TCNE and 1 h after the addition. The disappearance of absorption in NIR region indicates oxidation of $\mathrm{C}_{60}{ }^{-}$inside the cage. The identical spectrum to $\mathrm{C}_{60} @ \mathrm{Pd}_{2} 1_{4}$ with less intensity was obtained after 1 h . All the samples were prepared in the glove box filled with $\mathrm{N}_{2}$. Absorption spectra were measured by using DAD HP-8453 UV-Vis.

Figure 3.4.43 UV-Vis-NIR spectra ( $0.35 \mathrm{mM}, \mathrm{CD} 3 \mathrm{CN}, 295 \mathrm{~K}, \mathrm{I}=0.2 \mathrm{~cm}$ ) of $\mathrm{C}_{60}{ }^{-}$ $@ \mathrm{Pd}_{2} \mathrm{~L}_{4}$ (red line), after TCNE addition (gray line), 1 h after TCNE addition (yellow line), and $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{~L}_{4}$ (purple line)

Figure 3.4.44 ${ }^{1} \mathrm{H}$ NMR spectra ( $0.70 \mathrm{mM}, \mathrm{CD}_{3} \mathrm{CN}, 500 \mathrm{MHz}$ ) of $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{LP}_{4}$ (bottom) and after photochemical reduction and re-oxidation by using TCNE (top)

### 3.4.8 X-Band EPR spectra and simulations

### 3.4.8.1 EPR control experiments

The following experiments and analyses were performed by Shari L. Meichsner in the Kasanmascheff group. In addition, the following detail description of the experiments and analyses was contributed by Shari L. Meichsner. To ensure that the encapsulated $\mathrm{C}_{60}{ }^{-}$- is the only radical species detected, three control experiments were performed (Figure 3.4.45). The host-guest complex without BNAH was measured before (blue) and after (yellow) irradiation. These samples did not result in any detectable EPR signals. Similarly, irradiation of $\mathrm{Pd}_{2} \mathrm{~L}_{4}$ together with BNAH showed no EPR signal (black). The irradiated host-guest assembly $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{~L}_{4}$ was the only sample that displayed a sharp EPR signal (red).

Figure 3.4.45 Control EPR experiments of different compounds, performed at X-Band under aerobic conditions. The only signal obtained arises after irradiation of $\mathrm{C}_{60} @ \mathrm{Pd}_{2} 1_{4}$ in acetonitrile ( $0.35 \mathrm{mM}, 0.50 \mathrm{~mL}, 0.17 \mu \mathrm{~mol}$ ) in the presence of BNAH (10 $\mathrm{mM}, 8.8 \mu \mathrm{~L}, 0.08 \mu \mathrm{~mol}$ ). Experimental conditions are: 0.32 mW power, 1 G modulation amplitude, 100 kHz modulation frequency, 1.28 ms as time constant, 15.0 ms conversion time, 1 scan.

### 3.4.8.2 Simulations of X-Band EPR spectra

X-band EPR measurements were carried out at $\mathrm{T}=100 \mathrm{~K}$ using a Bruker EMX-Nano Benchtop spectrometer equipped with a continuous-flow nitrogen cryostat (Figure 3.4.46). Spectral simulations were performed with the EasySpin 5.2.28 ${ }^{[50]}$ 'pepper' routine.

Figure 3.4.46 X-Band EPR spectra of $\mathrm{C}_{60}{ }^{\circ} @ \mathrm{Pd}_{2} \mathrm{~L}_{4}$ in acetonitrile ( 0.35 mM ) prepared under $\mathrm{N}_{2}$ atmosphere (a) and aerobic conditions (b) are shown with their corresponding simulations (red). Spectrum shown in (a) was simulated via using following parameters; $S=1 / 2$ species with $g_{i s o}=1.999$ and 1.1 mT linewidth (red in (a) and blue in (b)). For simulations of (b) an additional second species (yellow) was taken into an account with $g_{\text {iso }}=2.001,0.3 \mathrm{mT}$ linewidth. A yellow-to-blue ratio of 1 resulted in the complete simulation of $\mathrm{C}_{60} 0^{\circ} @ \mathrm{Pd}_{2} \mathrm{~L}_{4}$ prepared under aerobic conditions. Dotted lines indicate the positions of the $g$-values of the respective species. Experimental conditions are: 0.79 mW power, 1 G modulation amplitude, 100 kHz modulation frequency, 1.28 ms as time constant, 15.0 ms conversion time, and 20 scans.

### 3.4.8.3 Half-lifetime determination via X-Band EPR measurements

EPR signal intensity is dependent on the relaxation properties of the paramagnetic species under investigation and used microwave powers. Therefore, power saturation curves are plotted for $\mathrm{C}_{60}{ }^{\circ} @ \mathrm{Pd}_{2} 1_{4}$ in acetonitrile ( 0.35 mM ) prepared under $\mathrm{N}_{2}$ atmosphere and aerobic conditions (Figure 3.4.47). The results clearly demonstrated
the distinct relaxation properties of $\mathrm{C}_{60}{ }^{-}$and the oxygenated species. Microwave powers higher than 0.8 mW led to saturation of the oxygenated species, whereas $\mathrm{C}_{60^{-}}$was not saturated in the observed range. This enabled us, firstly, to separate EPR signals of $\mathrm{C}_{60}{ }^{\circ}$ and the oxygenated species via measurements recorded at 0.79 and 79.43 mW (Figure 3.4.47b-c); and secondly, to determine the half-lifetime of both radicals by tracing the decay of the peak-to-peak amplitude of the EPR signals. The half-lifetime of encapsulated $\mathrm{C}_{60}{ }^{\circ}$ under aerobic conditions was estimated to be 14 mins, in excellent agreement with the UV-Vis-NIR results under the same aerobic conditions. The half-lifetime of encapsulated $\mathrm{C}_{60}{ }^{\circ-}$ under anaerobic condition shows a significantly longer value of 893 mins. To determine this value, duplicates from two different sample preparations were measured for the encapsulated $\mathrm{C}_{60^{\circ-}}$ under anaerobic conditions and the mean values were plotted together with their standard deviation. We denote the longer half-lifetime determined by EPR as compared to UV-Vis-NIR measurements ( $\sim 300 \mathrm{~min}$ ) to the different sample preparation conditions: In both cases, samples were prepared similarly in the glovebox. The UV-Vis-NIR measurements were performed in a stoppered cuvette outside the glovebox, keeping the sample at room temperature. Therefore, contamination from the surrounding air during the measurement period cannot be excluded, shortening the detected halflifetime. In contrast, for the EPR measurement, the sample remained in the glovebox and aliquots were taken after indicated times, removed from the glovebox in sealed EPR tubes, immediately deep-frozen in liquid nitrogen and measured immediately, making additional radical degradation by oxygen contamination less likely. It is worth noting that EPR was able to detect the signal of the encapsulated fullerene radical in the low micromolar range even after the solution was kept for four weeks at 303 K inside the glove box (Figure 3.4.47c).

Figure 3.4.47 (a) Continuous-wave power saturation curves for $\mathrm{C}_{60} 0^{-} @ \mathrm{Pd}_{2} \mathrm{~L}^{\mathrm{P}} \mathrm{H}_{4}$ in acetonitrile $(0.35 \mu \mathrm{M})$ and its oxygenated species. Experiments shown in Figure 6 and S37 were recorded at 0.79 mW power (blue point in a), which is the ideal power for detecting both species. The lower spectrum shown in (b) was acquired with 79 mW power (red point in a) and shows the encapsulated $\mathrm{C}_{60^{\circ}}$, only. The time-dependent EPR spectra of $\mathrm{C}_{60}{ }^{\circ} @ \mathrm{Pd}_{2} 1_{4}$ prepared under aerobic conditions and in $\mathrm{N}_{2}$ atmosphere are used to calculate the half-lifetime (c) of the encapsulated $\mathrm{C}_{60}{ }^{\circ-}$ radical anion (aerobic: 14 min , anaerobic 893 min ). The data were normalized by dividing double integral values of each spectrum by the maximum obtained value. Experimental conditions are: 79.43 mW power, 1 G modulation amplitude, 100 kHz modulation frequency, 1.28 ms as time constant, 15.0 ms conversion time, 20 to 100 scans.

## 4 Encapsulation Capability of a Triptycene-Based Pd2L4 Coordination Cage towards carbon-rich guests

## Abstract:

The encapsulation capability of a triptycene-based Pd2L4 coordination cage was investigated. The cage was found to encapsulate two molecules of corannulene and various $\mathrm{C}_{60}$ derivatives. Extraction of encapsulated $\mathrm{PC}_{61} \mathrm{BM}$, one of the most studied $\mathrm{C}_{60}$ derivative in organic photovoltaics, from the cage was performed by the addition of $\mathrm{CS}_{2}$ into an acetonitrile solution of the $\mathrm{PC}_{61} \mathrm{BM}$ encapsulating cage. This extraction process can be performed in a layer-to-layer fashion. Thus, the recovered cage can be further used for $\mathrm{PC}_{61} \mathrm{BM}$ encapsulation and the following extraction process.

### 4.1 Introduction

Figure 4.1.1 Schematic illustration of (a) encapsulation of two corannulene molecules and (b) encapsulation of a C60 derivative

Fullerene $\mathrm{C}_{60}$ is a globular-shaped allotrope of carbon utilized in a variety of fields. ${ }^{[1]}$ For example, $\mathrm{C}_{60}$ and its derivatives have been used as an electron accepting material in organic solar cells. ${ }^{[2]}$ Manipulation of the molecular orbital energies of fullerene derivatives is a crucial factor to tune the efficiency of charge transfer processes in such photovoltaic devices. ${ }^{[3]}$ Many chemical reactions to modify $\mathrm{C}_{60}$ have been developed because such chemical modifications can tune its electronic properties, solubility, and packing manner in molecular composites. ${ }^{[4,5]}$ For example, $\mathrm{PC}_{61} \mathrm{BM}$ is one of the most utilized $\mathrm{C}_{60}$ derivatives as an electron accepting and transporting material. ${ }^{[6]}$ Although, covalent modification is a forthright method to manipulate the electronic properties of $\mathrm{C}_{60}$, stereochemical control of chemical modifications of $\mathrm{C}_{60}$ is often difficult due to a similar reactivity of pristine $\mathrm{C}_{60}$ and its derivatives, resulting in the formation of multiadduct isomers. ${ }^{[6,7]}$ To facilitate chemical modification with regio-selectivity, a variety of strategies have been developed such as tether-directed syntheses and supramolecular-mask methods. ${ }^{[8-15]}$ In the first strategy, the choice of substrate which has more than two reactive sites with $\mathrm{C}_{60}$ is a key point. First, the substrate reacts with $\mathrm{C}_{60}$ via one of the reactive sites. The length and the flexibility of the substrate defines the regio-selectivity of the following intramolecular addition. In the latter strategy, chemical modification of encapsulated $\mathrm{C}_{60}$ inside a host molecule facilitates regioselectivity. The host molecule provides steric bulk to the confined $\mathrm{C}_{60}$ preventing it from random addition of multiple substrates on to the $\mathrm{C}_{60}$. The encapsulation of $\mathrm{C}_{60}$ derivative inside coordination cages has been reported. ${ }^{[16-18]}$ Amongst them, the coordination cages reported by Ribas and Yoshizawa display encapsulation and release of $\mathrm{C}_{60}$ derivatives. ${ }^{[16,18]}$

Well-established purification methods for $\mathrm{C}_{60}$ derivatives are largely limited to chromatographic separation, and thus, there is a space to be explored. Recently, the Clever group has reported several coordination cages based on organic ligands having a curved $\pi$-surface as shown in the chapters above. ${ }^{[19-21]}$ These hosts provide a suitable cavity to accommodate $\mathrm{C}_{60}$ or $\mathrm{C}_{70}$ through $\pi^{-\pi}$ interactions. Strong encapsulation of fullerenes inside these coordination cages allows for a variety of applications as shown in Chapters $1 \& 3 .{ }^{[22]}$

Some coordination cages composed of ligands with curved $\pi$-surfaces show unique guest binding behaviors. ${ }^{[23]}$ Therefore, it can be presumed that $\mathrm{Pd}_{2} \mathrm{~L}^{\mathrm{P}} 4$ should be able to encapsulate not only $\mathrm{C}_{60}$, but also other guest compounds such as polyaromatic hydrocarbons and $\mathrm{C}_{60}$ derivatives. Based on this idea, the encapsulation capability of $\mathrm{Pd}_{2} \mathrm{~L}^{\mathrm{P}_{4}}$ was investigated (Figure 4.1.1). As a result, $\mathrm{Pd}_{2} \mathrm{~L}^{\mathrm{P}} 4$ was found to be able to encapsulate two molecules of corannulene (Figure 4.1.1a). In addition, $\mathrm{Pd}_{2} \mathrm{~L}_{4}$ showed an accommodation capability towards various $\mathrm{C}_{60}$ derivatives such as PC61BM (Figure 4.1.1b). Encouraged by the observation that $\mathrm{Pd}_{2} \mathrm{~L}_{4}$ can encapsulate $\mathrm{PC}_{61} \mathrm{BM}$ but not $\mathrm{PC}_{62} \mathrm{BM}$, a bis-adduct of $\mathrm{PC}_{61} \mathrm{BM}$, a facile yet non-disruptive method to liberate encapsulated $\mathrm{PC}_{61} \mathrm{BM}$ from $\mathrm{Pd}_{2} \mathrm{~L}_{4}$ was explored.

### 4.2 Results and discussion

(a) $\mathrm{Pd}_{2} \mathrm{LP}_{4}$
(b)

Figure 4.2.1 ${ }^{1} \mathrm{H}$ NMR spectrum of (a) $\mathrm{Pd}_{2} \mathrm{~L}_{4}$ with perylene $\left(\mathrm{CD}_{3} \mathrm{CN}, 0.70 \mathrm{mM}, 600\right.$ $\mathrm{MHz}, 298 \mathrm{~K}$ ) (b) $\mathrm{Pd}_{2} \mathrm{~L}_{4}$ with coronene ( $\mathrm{CD}_{3} \mathrm{CN}, 0.70 \mathrm{mM}, 600 \mathrm{MHz}, 298 \mathrm{~K}$ ) and (c) $\mathrm{Pd}_{2} \mathrm{LP}_{4}\left(\mathrm{CD}_{3} \mathrm{CN}, 0.70 \mathrm{mM}, 500 \mathrm{MHz}, 298 \mathrm{~K}\right)$

The triptycene-based $\mathrm{Pd}_{2} \mathrm{~L}_{4}$ coordination cage was synthesized following the previous work aforementioned in Chapter 3. ${ }^{[22]}$ The investigation of the guest scope of $\mathrm{Pd}_{2} \mathrm{~L}^{\mathrm{P}} 4$ started with small polyaromatic hydrocarbons (PAHs; Figure 4.2.1). Perylene, coronene and corannulene were tested for encapsulation. Among those molecules, only corannulene, known as a substructure of $\mathrm{C}_{60}$, was incarcerated within the cage (Figure 4.2.2a) while coronene and perylene cannot be encapsulated. Specifically, an excess amount of solid corannulene was added into an acetonitrile solution of $\mathrm{Pd}_{2} \mathrm{~L}_{4}$ and heated at $70^{\circ} \mathrm{C}$ for 24 h . In the ${ }^{1} \mathrm{H}$ NMR spectrum, a new set of signals assignable to (Cor) ${ }_{2} @ \mathrm{Pd}_{2} \mathrm{LP}_{4}$ by NMR analyses was observed besides empty $\mathrm{Pd}_{2} \mathrm{LP}_{4}$. It was found that encapsulation of corannulene takes place pairwise in a cooperative manner with an exchange rate slower than the NMR time scale (Figure 4.2.2b). Two molecules of corannulene were found to be encapsulated inside $\mathrm{Pd}_{2} \mathrm{~L}^{\mathbf{P}} 4$ according to the ${ }^{1} \mathrm{H}$ NMR signal integration ratio between the cage and the encapsulated corannulenes signals
as well as the results of an NOESY experiment (Figure 4.2.2c). Furthermore, a prominent signal assignable to (Cor) ${ }_{2} @ \mathrm{Pd}_{2} \mathrm{LP}_{4}$ was also observed in the ESI-MS spectrum (Figure 4.4.33). Note that, the signals of free $\mathrm{Pd}_{2} \mathrm{~L}_{4}$ showed slightly different chemical shifts compared with the cage measured without corannulene. It can be assumed that this is originated from encapsulation of single corannulene with fast exchange between free corannulene. The ${ }^{1} \mathrm{H}$ NMR signal of the encapsulated corannulene guests appeared at 5.47 ppm . Comparing to the free corannulene, the signal of the encapsulated corannulenes showed an upfield shift by 2.42 ppm in acetonitrile, similar to what was observed in other reports. ${ }^{[23,24]}$ In addition, the $\mathrm{H}^{\mathrm{a}}$ signal of the pyridine coordination-sites which are supposed to be pointing inward the cavity also showed an upfield shift by 3.12 ppm , most likely due to interactions between the encapsulated corannulenes and these hydrogens, further supporting the encapsulation of corannulenes inside the cavity, not outside. ${ }^{[22]}$

Figure 4.2.2 (a) Encapsulation of corannulene into $\mathrm{Pd}_{2} \mathrm{~L}^{4}$ (b) ${ }^{1} \mathrm{H}$ NMR spectrum ( $\mathrm{CD}_{3} \mathrm{CN}, 500 \mathrm{MHz}, 298 \mathrm{~K}$ ) of $\mathrm{Pd}_{2} \mathrm{~L}_{4}$ (top) and (Cor) ${ }_{2} @ \mathrm{Pd}_{2} \mathrm{~L}_{4}$ (bottom) (c) ${ }^{1} \mathrm{H}-{ }^{1} \mathrm{H}$ NOESY spectrum ( $\mathrm{CD}_{3} \mathrm{CN}, 500 \mathrm{MHz}$, 298 K ) of (Cor) $)_{2} @ \mathrm{Pd}_{2} \mathrm{~L}_{4}$

Figure 4.2.3 ${ }^{1} \mathrm{H}$ NMR spectrum ( $\mathrm{CD}_{3} \mathrm{CN}, 500 \mathrm{MHz}$ ) of (Cor) ${ }_{2} @ \mathrm{Pd}_{2} \mathrm{~L}^{\mathrm{P}_{4}}$ at 303 K (top) and at 263 K (bottom)

In addition, DOSY analyses showed that the encapsulated corannulenes have a smaller diffusion coefficient compared with free corannulene in this acetonitrile solution (Figure 4.4.31). Furthermore, encapsulation of corannulenes was found to be temperature dependent. Upon cooling, the ratio of (Cor) ${ }_{2} @ \mathrm{Pd}_{2} \mathrm{LP}_{4}$ increased from 39 $\% ~(303 \mathrm{~K})$ up to $77 \%$ ( 253 K , both at 0.70 mM cage concentration and excess of solid corannulene). During the VT- ${ }^{1} \mathrm{H}$ NMR experiment, a host-guest complex of $\mathrm{Pd}_{2} \mathrm{~L}_{4}$ and single corannulene, Cor@Pd $L^{P_{4}}$, was not independently observed on the NMR time scale (Figure 4.2.3). To further investigate the dynamic behavior of guest exchange, a ${ }^{1} \mathrm{H}$ NMR titration experiment was conducted. An acetonitrile solution of corannulene was titrated into an acetonitrile solution of $\mathrm{Pd}_{2} \mathrm{~L}^{\mathrm{P}_{4}}$ in an NMR tube. As a result, all of the peaks from $\mathrm{Pd}_{2} \mathrm{~L}_{4}$ showed slight shifts $\left(\Delta \delta_{\max }=0.02 \mathrm{ppm}\right)$ with the appearance of (Cor) ${ }_{2} @ \mathrm{Pd}_{2} \mathrm{LP}_{4}$ over the addition of 7 eq. of corannulene (Figure 4.2.4). These results indicate that encapsulation of single corannulene is in a fast equilibrium most likely due to the weak encapsulation of single corannulene, while a pair of corannulenes is bound in slow exchange (Figure 4.2.5).

Figure 4.2.4 ${ }^{1} \mathrm{H}$ NMR spectrum $\left(\mathrm{CD}_{3} \mathrm{CN}, 500 \mathrm{MHz}, 298 \mathrm{~K}\right)$ of $\mathrm{Pd}_{2} \mathrm{~L}_{4}$ without corannulene (top) and with 7 eq. of corannulene (bottom)

To gain additional insight into this process, DFT calculations at the M06-2X/Lanl2dz level of theory were performed. As a result, encapsulation of two corannulenes was implied to be a more favorable process than single corannulene encapsulation (Table 4.4.2). The energy gain of the two corannulenes encapsulation process was more than two-times larger than the single corannulene encapsulation in $\mathrm{Pd}_{2} \mathrm{~L}^{\mathbf{P}}$. In the obtained geometry, convex-concave interactions between the encapsulated corannulenes and the ligands were implied. As shown above, perylene and coronene cannot be encapsulated inside the cage. This is probably due to lack of such convex-concave interactions with the curved triptycene ligands.

Figure 4.2.5 Schematic illustration of the kinetic of corannulene encapsulation into $\mathrm{Pd}_{2} \mathrm{~L}^{\mathbf{P}}$; the optimized geometries at M06-2X/Lanl2dz level of theory are shown for Cor@Pd2L $\mathbf{P}_{4}$ and (Cor)2@Pd2LP ${ }_{4}$

2-4@ $\mathrm{Pd}_{2} \mathrm{~L}^{\mathrm{P}} 4$

Figure 4.2.6 (a) Encapsulation of 2-4 into $\mathrm{Pd}_{2} \mathrm{~L}_{4}$ (b) chemical structure of 2-4 with encapsulation ratio

Next, encapsulation of a variety of $\mathrm{C}_{60}$ derivatives inside $\mathrm{Pd}_{2} \mathrm{~L}_{4}$ was investigated (Figure 4.2.6). $\mathrm{C}_{60}$ derivatives were added in an acetonitrile solution of $\mathrm{Pd}_{2} \mathrm{~L}_{4}$ and the suspension was stirred at $70^{\circ} \mathrm{C}$ for 48 h . Afterwards, the residual solid $\mathrm{C}_{60}$ derivatives were removed by filtration. $\mathrm{C}_{60}$ derivatives 2-4 were encapsulated in 87-100\% yield determined by ${ }^{1} \mathrm{H}$ NMR analyses measured at room temperature (Figure 4.2.7a). In the ${ }^{1} \mathrm{H}$ NMR spectra of the host-guest complexes, a new set of signals was observed in addition to empty $\mathrm{Pd}_{2} \mathrm{~L}^{\mathbf{P}}$. The host-guest complexes should have a lower symmetry than the parental host because of the bulky substituent on the $\mathrm{C}_{60}$ derivatives. As shown in Figure 4.2.7a, as expected, in the ${ }^{1} \mathrm{H}$ NMR spectra of $\mathbf{2 - 4 @ P d _ { 2 } L ^ { P } 4 \text { , two sets }}$ and four sets of signals were observed for the pyridine coordination-site and the triptycene-backbone protons, respectively, which supports the encapsulation of the $\mathrm{C}_{60}$ derivatives (Figure 4.4.2, Figure 4.4.8, and Figure 4.4.16). In addition, ${ }^{1} \mathrm{H}$ DOSY NMR analyses showed that all of the new signals belong to a single species, having a comparable hydrodynamic radius to $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{~L}_{4}$ (Figure 4.4.5, Figure 4.4.13 and Figure 4.4.21). ${ }^{[22]}$ The formation of the $2-4 @ P_{2} L^{P} 4$ host-guest complexes was further supported by ESI-MS analyses (Figure 4.2.7b, Figure 4.4.7, Figure 4.4.15, and Figure 4.4.23). Further, the small space in between the ligands found in the modelled geometry of $2 @ P_{2} L^{P_{4}}$ implies that encapsulation of bis-adducts, which can be obtained as side-products of synthesis of $\mathrm{C}_{60}$ derivatives, should be sterically difficult (Figure 4.2.8 a-b). As can be seen in the DFT optimized molecular model, four ligands should be forced to gather to make the large enough window for the bulky substituent of 4 (Figure 4.2.8c), which should exclude encapsulation of $\mathrm{PC}_{62} \mathrm{BM}$. According to this
assumption, an excess amount of solid $\mathrm{PC}_{62} \mathrm{BM}$, a bis-adduct of 4 commercially available as a mixture of regio-isomers, was heterogeneously mixed in an acetonitrile solution of $\mathrm{Pd}_{2} \mathrm{LP}_{4}$ for 24 h at $70{ }^{\circ} \mathrm{C}$. After heating, the residual solid $\mathrm{PC}_{62} \mathrm{BM}$ was removed by filtration. In the ${ }^{1} \mathrm{H}$ NMR spectrum of the resulting filtrate, only one set of signals of empty $\mathrm{Pd}_{2} \mathrm{~L}_{4}$ was observed. (Figure 4.4.43 and Figure 4.4.45) Therefore, probably due to steric reasons, encapsulation of $\mathrm{PC}_{62} \mathrm{BM}$ is not likely possible. This result implies that $\mathrm{Pd}_{2} \mathrm{~L}_{4}$ preferably encapsulates $\mathrm{C}_{60}$ mono-adducts over their bisadducts. Indeed, only $4 @ P_{2} L^{P_{4}}$ was obtained as a major species in $66 \%$ yield when 2.5 equivalent of 4 and $\mathrm{PC}_{62} \mathrm{BM}$ each were dispersed into an acetonitrile solution of $\mathrm{Pd}_{2} \mathrm{~L}_{4}$ in the presence of minute amount of $\mathrm{CS}_{2}$ (Figure 4.4.46).

Figure 4.2 .7 (a) ${ }^{1} \mathrm{H}$ NMR spectra ( $\mathrm{CD}_{3} \mathrm{CN}, 0.35 \mathrm{mM}, 500 \mathrm{MHz}, 298 \mathrm{~K}$ ) of 2-4@Pd2L ${ }_{4}$; (b) ESI-MS spectra (positive) of 2-4@ $\mathrm{Pd}_{2} \mathrm{~L}_{4}$ with calculated isotopic patterns

Figure 4.2.8 The optimized geometry of $4 @ \mathrm{Pd}_{2} \mathrm{~L}_{4}$ at $\mathrm{B} 3 \mathrm{LYP} / 6-31 \mathrm{G}(\mathrm{d})$ for the elements C, H, N, and O and B3LYP/Lanl2dz for Pd (a) the opposite side of the chemical appendix of $\mathrm{PC}_{61} \mathrm{BM}$ and (b) on the side of the chemical appendix and (c) the view from top

Take it into account that, the yield of $4 @ P_{d} L P_{4}$ was $87 \%$ while the quantitative formation of 2@Pd $L^{P_{4}}$ was observed, there should be an equilibrium between the encapsulated guest and the free guest slightly solubilized in the acetonitrile solution. In many cases, encapsulation of guest molecules in a very polar solvent are highly affected by solvophobic interactions. Hydrophobic organic guests tend to be captured inside a non-polar cavity rather than being solvated. ${ }^{[25]}$ Thus, simple addition of a better solvent for the C60 derivatives to the host-guest complex solution was tested with the aim that the equilibrium between the confined guest and the free guest should lean towards releasing of the guest molecule into the mixed solvent.
Based on this hypothesis, we tried various organic solvents which are commonly employed to solubilize $\mathrm{C}_{60}$. Among those organic solvents, addition of $\mathrm{CS}_{2}$ was found to extract encapsulated guest 4 into the solvent from the cage. 26 vol\% of $\mathrm{CS}_{2}$ was added to an acetonitrile solution of $4 @ \mathrm{Pd}_{2} \mathrm{~L}^{4}$ and the mixture was shaken for several seconds and let stand for several minutes (Figure 4.2.9). After this resting time, two layers were obtained, where the upper layer is a transparent acetonitrile solution of the empty host and the bottom layer is a reddish $\mathrm{CS}_{2}$ solution containing the extracted compound 4. The purity of extracted 4 was confirmed by ${ }^{1} \mathrm{H}$ NMR measurement (Figure 4.4.42). The acetonitrile solution recovered from the upper layer was found to contain intact $\mathrm{Pd}_{2} \mathrm{~L}_{4}$, which shows that this method is non-disruptive (Figure 4.2.9).

Figure 4.2.9 ${ }^{1} \mathrm{H}$ NMR spectra ( $\mathrm{CD}_{3} \mathrm{CN}, 500 \mathrm{MHz}, 298 \mathrm{~K}$ ) showing repetitive uptake and release of 4 using $\mathrm{Pd}_{2} \mathrm{~L}^{\mathrm{P}_{4}}$

Thus, we tackled repetitive encapsulation and extraction of 4 for 4 cycles (Table 4.2.1). After extracting 4 from $4 @ \mathrm{Pd}_{2} \mathrm{~L}^{\mathrm{P}}$, the mixture was cooled to $-78^{\circ} \mathrm{C}$ and the CS layer was removed by decanting. The recovered acetonitrile solution of $\mathrm{Pd}_{2} \mathrm{~L}_{4}$ was further tested for the further cycles. As a result, $\mathrm{Pd}_{2} \mathrm{LP}_{4}$ was proven to encapsulate and liberate 4 in a recycling yet non-disruptive manner. However, the decline of the encapsulation ratio was observed over repetitive cycles. It is presumed that the
observed decrease of the encapsulation ratio can be attributed to a slight miscibility of $\mathrm{CS}_{2}$ in the acetonitrile solution.

Table 4.2.1 Recycling encapsulation and release of 4 using $\mathrm{Pd}_{2} \mathrm{~L}_{4}$; the yields were determined by ${ }^{1} \mathrm{H}$ NMR analyses

| Cycle | Yield (\%) |
| :---: | :---: |
| 1st | 80.5 |
| 2nd | 80.3 |
| 3rd | 62.9 |
| 4th | 52.2 |

### 4.3 Conclusion

The encapsulation capability of coordination cage $\mathrm{Pd}_{2} \mathrm{LP}_{4}$ towards corannulene and various $\mathrm{C}_{60}$-derivatives has been investigated. The curved $\pi$-surface of the triptycenebackbone of $L^{P}$ facilitates a nanoscopic cavity in which a variety of curved aromatic compounds can be encapsulated in high to quantitative yields. $\mathrm{Pd}_{2} \mathrm{~L}_{4}$ showcases the encapsulation of two molecules of corannulene in acetonitrile. In addition, $\mathrm{Pd}_{2} \mathrm{~L}_{4}$ encapsulates mono-adducts of $\mathrm{C}_{60}$ 2-4 leading to a host-guest complex having a lower symmetry. Uptake and extraction of 4 using $\mathrm{Pd}_{2} \mathrm{~L}^{\mathrm{P}_{4}}$ were demonstrated in a recycling way. The uptake and extraction process can be accomplished in a layer-to-layer fashion by using two different solvents. Furthermore, $\mathrm{Pd}_{2} \mathrm{LP}_{4}$ was found not to encapsulate bis-adducts of fullerene derivatives such as $\mathrm{PC}_{62} \mathrm{BM}$, which should make $\mathrm{Pd}_{2} \mathrm{~L}^{\mathrm{P}}$ a candidate for sustainable fullerene mono-adduct purification systems.

### 4.4 Appendix

### 4.4.1 Materials and methods

Unless otherwise stated, all chemicals were purchased from commercial sources and used as received. $\left[\mathrm{Pd}(\mathrm{MeCN})_{4}\right]\left(\mathrm{BF}_{4}\right)_{2}, \mathbf{2 - 4}$, and $\mathrm{PC}_{62} \mathrm{BM}$ as a mixture of isomers were purchased from Sigma-Aldrich. Corannulene was purchased from TCI.inc. Bruker ESI-timsTOF and compact mass spectrometers using Agilent tune mix as calibrant. NMR experiments were performed using Bruker AV 500 Avance NEO, Bruker AV 600 Avance FT-NMR, Bruker Avance III HD 700 MHz spectrometers. ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ signals were referenced to the residual solvent peak: acetonitrile (1.94 ppm,118.26 ppm), chloroform (7.26 ppm). DFT calculation were performed using Gaussian Gaussian 16, Revision B.01. ${ }^{[26]}$ Hydrodynamic radii of compounds were calculated from Stokes-Einstein equation (eq 1) where $D$ is a diffusion coefficient, $k_{B}$ is Boltzman constant, $T$ is a temperature, $\eta$ is a viscosity of the solvent, and $r_{H}$ is a hydrodynamic radius of interest. ${ }^{1} \mathrm{H}$ DOSY NMR spectra were recorded with a dstebpgp3s pulse sequence with diffusion delays D20 of 0.08 s and gradient powers P30 of 1200. $T_{1}$ analyses of the corresponding signals in the 1D spectra were performed to obtain the diffusion coefficients $D$ using the STEJSKAL-TANNEREquation.

$$
D=\frac{k_{B} T}{6 \pi n r_{H}}(\text { eq } 1)
$$

### 4.4.2 Encapsulation of $\mathrm{C}_{60}$ derivatives into $\mathrm{Pd}_{2} \mathrm{~L}_{4}$

Figure 4.4.1 Encapsulation of guest molecules into $\mathrm{Pd}_{2} \mathrm{~L}_{4}$

General procedure: To an acetonitrile solution of $\mathrm{Pd}_{2} \mathrm{LP}_{4}(0.35 \mathrm{mM}, 1.0 \mathrm{~mL}, 0.35$ $\mu \mathrm{mol})$, synthesized following the literature, ${ }^{[22]}$ in a vial was added an excess amount of solid guest. The heterogenous mixture was stirred under heating at $70^{\circ} \mathrm{C}$ for 24 h and NMR measurements were carried out. The encapsulation ratio was estimated from the ${ }^{1} \mathrm{H}$ NMR integral ratio.

### 4.4.3.2.7 VT- ${ }^{1} \mathrm{H}$ NMR spectra of (Cor) ${ }_{2} @ \mathrm{Pd}_{2} \mathrm{LP}_{4}$

VT- ${ }^{1} \mathrm{H}$ NMR was carried out in a range of 253-343 K. Once temperature is set at a desired temperature, the sample was let stand for 10 mins in the NMR spectrometer to achieve an equilibrium state. The encapsulation ratio at each temperature was calculated from the ${ }^{1} \mathrm{H}$ NMR integral values of empty $\mathrm{Pd}_{2} \mathrm{~L}^{\mathrm{P}_{4}}$ and (Cor) $)_{2} @ \mathrm{Pd}_{2} \mathrm{~L}^{\mathrm{P}_{4}}$. The results are summarized in the table below.

Figure 4.4.34 VT- ${ }^{-1} \mathrm{H}$ NMR spectra $\left(\mathrm{CD}_{3} \mathrm{CN}, 500 \mathrm{MHz}\right)$ of (Cor) ${ }_{2} @ \mathrm{Pd}_{2} \mathrm{~L}_{4}$ measured at various temperatures from 253-343 K

Table 4.4.1 Encapsulation ratio of corannulene in $\mathrm{Pd}_{2} \mathrm{~L}_{4}$ at various temperatures

### 4.4.3.3 Titration experiment

To an acetonitrile solution of $\mathrm{Pd}_{2} \mathrm{LP}_{4}(0.70 \mathrm{mM}, 0.600 \mathrm{~mL}, 0.42 \mu \mathrm{~mol})$ an acetonitrile solution of corannulene ( 10 mM ) was titrated. An aliquot of the stock solution of corannulene was added in the NMR tube where the acetonitrile solution of the cage was placed and the NMR tube was shaken before measuring. The encapsulated corannulene's signal appeared over the titration with a subtle difference in the chemical shift of the empty cage $\left(\Delta \delta_{\max }=-0.02 \mathrm{ppm}\right)$

Figure 4.4.35 ${ }^{1} \mathrm{H}$ NMR spectra ( $\mathrm{CD}_{3} \mathrm{CN}, 500 \mathrm{MHz}$, 298 K ) over titration of corannulene into $\mathrm{Pd}_{2} \mathrm{LP}_{4}$

### 4.4.3.4 DFT calculations

Figure 4.4.36 The optimized geometry of $\mathrm{Pd}_{2} \mathrm{~L}_{4}$ at $\mathrm{M} 06-2 \mathrm{X} / \mathrm{Lanl} 2 \mathrm{dz}$ level of theory in the gas-phase

Table 4.4.2 Summary of the total electronic energies

|  | Cor | Cage | (Cor)2@Cage | Cor@cage |
| :---: | :---: | :---: | :---: | :---: |
| $E[$ Hartree $]$ | - |  |  |  |
| 767.751686 | 7554.40071 | -9089.998854 | -8322.195748 |  |
| $\Delta E$ <br> $[H a r t r e e]$ | - | - | -0.094772 | -0.043352 |
| $\Delta E \mathrm{~kJ} / \mathrm{mol}$ | - | - | -248.82 | -113.82 |

$\Delta E$ Hartree values were calculated for Cor@Cage and (Cor)2@Cage as following:

$$
\Delta E=E_{(\text {Cor) }) @ \text { Cage }}-\left(E_{\text {Cage }}+\mathrm{n}^{\star} E_{\text {Cor }}\right)
$$

where $\mathrm{n}=1$ and 2 stands for Cor@Cage and (Cor)2@Cage respectively.

### 4.4.4 Uptake and release of 4 using $\mathrm{Pd}_{2} \mathrm{~L}_{4}$

Figure 4.4.40 Uptake and release of $\mathbf{4}$ using $\mathrm{Pd}_{2} \mathrm{~L}_{4}$

To an acetonitrile solution of $4 @ \mathrm{Pd}_{2} \mathrm{LP}_{4}(0.7 \mathrm{mM}, 2.0 \mathrm{~mL}, 1.4 \mu \mathrm{~mol}) 26 \mathrm{vol} \%$ of $\mathrm{CS}_{2}$ $(700 \mu \mathrm{~L})$ was added. The mixture was shaken for 1 min and let it stand. Afterwards, ${ }^{1} \mathrm{H}$ NMR spectrum of the upper layer $\left(\mathrm{CD}_{3} \mathrm{CN}\right)$ containing the cage was measured to confirm the liberation of 4 . The CS2 layer at the bottom was removed by decantation at $-78{ }^{\circ} \mathrm{C}$. The recovered acetonitrile solution of $\mathrm{Pd}_{2} \mathrm{~L}_{4}$ was stirred with solid-state 4 at ambient temperature. The same procedure was repeated 4 times. After $3^{\text {rd }}$ cycle, the encapsulation yield was inclined most likely due to miscible CS $_{2}$ in the acetonitrile solution. The yields for each cycle are summarized in Table 4.4.3.

### 4.4.4.1 ${ }^{1} \mathrm{H}$ NMR spectra showing uptake and release of 4

Figure 4.4.41 ${ }^{1} \mathrm{H}$ NMR spectra $\left(\mathrm{CD}_{3} \mathrm{CN}, 500 \mathrm{MHz}, 298 \mathrm{~K}\right)$ showing uptake and release of $\mathbf{4}$ by $\mathrm{Pd}_{2} \mathrm{LP}_{4}$

Table 4.4.3 Encapsulation yield after each cycle

| Cycle | Yields (\%) |
| :---: | :---: |
| $1^{\text {st }}$ | $\mathbf{8 0 . 5}$ |
| $2^{\text {nd }}$ | $\mathbf{8 0 . 3}$ |
| $3^{\text {rd }}$ | $\mathbf{6 2 . 9}$ |
| $4^{\text {th }}$ | $\mathbf{5 2 . 2}$ |

### 4.4.4.2 ${ }^{1} \mathrm{H}$ NMR spectrum of recovered 4

Figure 4.4.42 ${ }^{1} \mathrm{H}$ NMR spectrum $\left(\mathrm{CDCl}_{3}, 500 \mathrm{MHz}, 298 \mathrm{~K}\right)$ of recovered 4

### 4.4.5 Encapsulation of $\mathrm{PC}_{62} \mathrm{BM}$

To a vial where solid $\mathrm{PC}_{62} \mathrm{BM}$ (excess) as a mixture of isomers were placed an acetonitrile solution of $\mathrm{Pd}_{2} \mathrm{LP}_{4}(0.600 \mathrm{~mL}, 0.70 \mathrm{mM}, 0.42 \mu \mathrm{~mol})$ were added. The mixture was stirred at $70^{\circ} \mathrm{C}$ for 24 h and the resulting mixture was filtrated to remove the remaining solid guests.

### 4.4.5.1 ¹ H NMR spectra

Figure 4.4.43 ${ }^{1} \mathrm{H}$ NMR spectra $\left(\mathrm{CD}_{3} \mathrm{CN}, 500 \mathrm{MHz}, 298 \mathrm{~K}\right)$ of the sample after heating with $\mathrm{PC}_{62} \mathrm{BM}$ for 24 h at $70{ }^{\circ} \mathrm{C}$ (top) and empty $\mathrm{Pd}_{2} \mathrm{~L}^{2} 4$ (bottom, 0.70 mM )

Figure 4.4.44 ${ }^{1} \mathrm{H}$ NMR spectrum ( $500 \mathrm{MHz}, \mathrm{CD}_{3} \mathrm{CN}, 298 \mathrm{~K}$ ) of the sample after heating with $\mathrm{PC}_{62} \mathrm{BM}$ for 24 h at $70^{\circ} \mathrm{C}$ (top). Some of the ${ }^{1} \mathrm{H}$ NMR integration ratio of the cage differ from the theoretical values probably due to slightly solubilized $\mathrm{PC}_{62} \mathrm{BM}$

### 4.4.5.2 ESI MS spectrum

Figure 4.4.45 ESI MS spectrum (positive) of the sample after heating with $\mathrm{PC}_{62} \mathrm{BM}$ for 24 h. $\mathrm{Pd}_{2} \mathrm{~L}_{4}$ was observed as a major species while $\left[\left(\mathrm{PC}_{62} \mathrm{BM} \cdot \mathrm{Pd}_{2} \mathrm{~L}_{4}\right) \mathrm{BF}_{4}\right]^{3+}$ was observed with a negligible intensity.

### 4.4.5.3 Competition experiment

| 4 ( $\mathrm{PC}_{61} \mathrm{BM}$ ) |  |
| :---: | :---: |
| $\mathrm{PC}_{62} \mathrm{BM}$ |  |
| (2.5 eq. each) | , |
| $\begin{aligned} & \mathrm{CD}_{3} \mathrm{CN}^{2} / \mathrm{CS}_{2}(10: 1) \\ & \text { r.t., } 24 \mathrm{~h} \end{aligned}$ |  |
| 66\% | 4@Pd $\mathbf{1}_{4}$ |

To a vial where solid $4(1.1 \mathrm{mg}, 1.2 \mu \mathrm{~mol})$ and $\mathrm{PC}_{62} \mathrm{BM}(1.3 \mathrm{mg}, 1.2 \mu \mathrm{~mol})$ were placed an acetonitrile solution of $\mathrm{Pd}_{2} \mathrm{LP}_{4}(0.70 \mathrm{~mL}, 0.7 \mathrm{mM}, 0.49 \mu \mathrm{~mol})$ and $\mathrm{CS}_{2}(70 \mu \mathrm{~L})$ were added. The mixture was stirred at room temperature for 24 h and the resulting mixture was filtrated to remove the remaining solid guests. $4 @ P_{2} L^{P_{4}}$ was obtained in $66 \%$ yield determined by ${ }^{1} \mathrm{H}$ NMR analysis.

Figure 4.4.46 ${ }^{1} \mathrm{H}$ NMR spectrum of the sample after heating with 4 and $\mathrm{PC}_{62} \mathrm{BM}$ $\left(\mathrm{CD}_{3} \mathrm{CN} / \mathrm{CS}_{2}=10: 1,500 \mathrm{MHz}, 298 \mathrm{~K}\right)$ for 24 h at r.t. (bottom) and $\mathbf{4} @ \mathrm{Pd}_{2} \mathbf{1}_{4}$ (top) $\left(\mathrm{CD}_{3} \mathrm{CN}\right.$, $500 \mathrm{MHz}, 298 \mathrm{~K})$

### 4.4.5.4 Theoretical study

Figure 4.4.47 The optimized geometry of $4 @ \mathrm{Pd}_{2} \mathrm{LP}_{4}$ at B3LYP/6-31G(d,p) for $\mathrm{H}, \mathrm{C}, \mathrm{N}$, O atoms, Lanl2dz for Pd atoms in the gas-phase

## 5 Synthesis of $\left[\eta^{2}-\mathrm{C}_{60}(\mathrm{Pd}(0) \mathrm{L}) \mathrm{n}\right]$ by a supramolecular mask method

#### Abstract

: As shown in the previous chapters, triptycene-based coordination cage $\mathrm{Pd}_{2} \mathrm{~L}_{4}$ encapsulates $\mathrm{C}_{60}$ derivatives in a high to quantitative yield thanks to the apertures between the ligands. It was also found that the synthesis of $\left[\eta^{2}-\mathrm{C}_{60}(\operatorname{Pd}(0) \mathrm{L}) \mathrm{n}\right](\mathrm{n}=1,2)$ complexes is possible via coordination of the encapsulated $\mathrm{C}_{60}$ to $\operatorname{Pd}(0)$ through the window(s) by the simple addition of $\operatorname{Pd}(0)(\mathrm{dba})$ 2. In this complexation reaction, the cage serves as a bulky protecting group for the confined $\mathrm{C}_{60}$ to prevent the polymerization yielding $\left[\eta^{2}-\mathrm{C}_{60}(\mathrm{Pd}(0) \mathrm{L})_{n}\right]$. $\left[\eta^{2}-\mathrm{C}_{60}(\mathrm{Pd}(0) \mathrm{L})_{2}\right]$ complex could also be synthesized in, potentially, a regio-selective manner by changing the equimolar amount of the $\operatorname{Pd}(0)$ source. Based on these observations, a thianthrene-based ligand was newly designed and synthesized for stabilizing the formed $\eta^{2}-\mathrm{Pd}(0) \mathrm{n} \mathrm{C}_{60}$ complex inside the cage. The thianthrene-based ligand shows a unique self-assembly behavior stemming from an intrinsic molecular inversion motion. Resulting from the selfassembly of the thianthrene-based ligand and $\mathrm{Pd}(\mathrm{II})$ cations was a $\mathrm{Pd}_{3} \mathrm{~L}_{6}$ ring-shaped coordination ring, which represents an unprecedented homoleptic topology from ligands possessing an bite angle of ca. $0^{\circ}$. Upon encapsulation of $\mathrm{C}_{60}$, the ring-shaped complex is partially transformed into $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{~L}_{4}$ coordination cage most probably due to template-effect by $\mathrm{C}_{60}$. The stabilization effect on the formed $\left[\eta^{2}-\mathrm{C}_{60}(\operatorname{Pd}(0) \mathrm{L}) \mathrm{n}\right](\mathrm{n}=1$, 2) in situ inside the thianthrene-based coordination cage via coordination of the lonepair of the sulfur atoms was not observed. However, the cage-to-cage transformation owing to the inversion motion of the thianthrene ligand can be a new concept for synthesis of functional coordination cages.

### 5.1 Introduction

$30 \mathrm{C}=\mathrm{C}$ bonds

Organometallic polymer

- Catalytic activity
- Electron conductivity

Nagashima, H et al.,
J. Chem. Soc. Chem. Commun. 1992, 377-379.

Figure 5.1.1 Coordination of $\mathrm{C}_{60}$ to $\mathrm{Pd}(0)$ resulting in organometallic polymers
$\mathrm{C}_{60}$ derivatives mentioned in the previous chapter are mainly covalently modified with organic residues, while coordination to transition metals through m-electrons from $\mathrm{C}=\mathrm{C}$ bond can also modify the electronic property of $\mathrm{C}_{60} \cdot{ }^{[1]}$ Among them, $\mathrm{Pd}(0)-\mathrm{C}_{60}$ metalorganic polymers are of great interests owing to their catalytic activity in hydrogenation reaction, molecular absorption, and electron conductivity. ${ }^{[2]} \mathrm{C}_{60}$ is known to coordinate to $\operatorname{Pd}(0)$ as well as $\operatorname{Pt}(0)$ through $\mathrm{C}=\mathrm{C}$ bond in an $\eta^{2}$ fashion (Figure 5.1.1). ${ }^{[3,4]}$ The first example of $\mathrm{Pd}(0)-\mathrm{C}_{60}$ metalorganic polymers was reported in 1992 by mixing $\operatorname{Pd}(0)(\mathrm{dba})_{3}$ and $\mathrm{C}_{60}$ in toluene. ${ }^{[5]}$ The composition between $\operatorname{Pd}(0)$ and $\mathrm{C}_{60}$ can be varied by changing the equivalent of the $\operatorname{Pd}(0)$ source. The topology of the polymer is thus believed to change depending on the stoichiometry of the $\operatorname{Pd}(0)$ source from 1D-polymer to 3D-network (Figure 5.1.1). Although $\mathrm{C}_{60}-\mathrm{Pd}(0)$ polymers have been widely studied and are known to show interesting properties as mentioned above, investigations into the physical properties of $\left[\eta^{2}-\mathrm{C}_{60} \mathrm{Pd}(0)_{n}\right]$ on unimolecular level is hindered due to the inevitable polymerization. The first unimolecular $\mathrm{Pt}(0)-\mathrm{C}_{60}$ complex was synthesized in $1991{ }^{[3]}$ and its $\operatorname{Pd}(0)$ analogue in 1993. ${ }^{[4]}$ In these reports, half of the vacant sites of the $\mathrm{d}^{10}$ square-planar metals are coordinated by
triphenylphosphines in a cis-fashion. The cis-protection prevents the complexes from polymerization and destabilization. As an alternative of the cis-protecting group, introduction of steric protection of unimolecular $\left[\eta^{2}-\mathrm{C}_{60} \operatorname{Pd}(0)_{n}\right](n=1,2)$ by, i.e. supramolecular mask method, seems to be able to realize synthesis of unimolecular $\mathrm{C}_{60}-\mathrm{Pd}(0)$ complexes. In this chapter, synthesis of $\left[\eta^{2}-\mathrm{C}_{60} \mathrm{Pd}(0)_{n}\right](\mathrm{n}=1,2)$ by a supramolecular mask method will be showcased. The apertures of $\mathrm{Pd}_{2} \mathrm{~L}_{4}$ made it possible to render $\operatorname{Pd}(0)$ and the encapsulated $\mathrm{C}_{60}$ react to form the complex. An increase in the stoichiometry of the $\operatorname{Pd}(0)$ source yielded a regioselective formation of $\eta^{2}-\mathrm{C}_{60}$-bis- $\mathrm{Pd}(0)$-complex. Considering that the reaction between $\mathrm{C}_{60}$ and $\operatorname{Pd}(0)$ usually results in polymerization, the coordination cage serves as a protecting group to prevent polymerization by prohibiting further $\mathrm{C}_{60}$ addition onto the $\mathrm{Pd}(0)$ center. This method is strategically different from other unimolecular $\mathrm{C}_{60} \mathrm{Pd}(0)$ complexes in terms of the way of preventing polymerization.

### 5.2 Results and discussion

(a)

(b)

Figure 5.2.1 (a) Synthesis of $\eta^{2}-\mathrm{C}_{6} \mathrm{Pd}(0) @ \mathrm{Pd}_{2} \mathrm{~L}_{4}(\mathrm{~b}){ }^{1} \mathrm{H}$ NMR spectrum $\left(\mathrm{CD}_{3} \mathrm{CN}, 500\right.$ $\mathrm{MHz}, 298 \mathrm{~K}$ ) of $\eta^{2}-\mathrm{C}_{6} \mathrm{Pd}(0) @ \mathrm{Pd}_{2} \mathrm{LP}_{4}$

Figure 5.2.2 ESI MS spectrum (positive mode) of $\eta^{2}-\mathrm{C}_{60} \mathrm{Pd}(0) @ \mathrm{Pd}_{2} \mathrm{~L}^{\mathrm{P}} 4$

The first synthesis of $\eta^{2}-\mathrm{C}_{60} \mathrm{Pd}(0)$ complex inside $\mathrm{Pd}_{2} \mathrm{~L}_{4}$ was achieved serendipitously. While reproducing the result of the $\mathrm{C}_{60}$ radical anion generation inside $\mathrm{Pd}_{2} \mathrm{~L}^{\mathrm{P}}$, an unusual greenish solution was obtained. ESI-MS analysis revealed a formation of $\eta^{2}-\mathrm{C}_{60} \mathrm{Pd}(0) @ \mathrm{Pd}_{2} \mathrm{~L}^{\mathrm{P}}$. This unprecedented result was assumed due to reduction of unreacted $\mathrm{Pd}(\mathrm{II})$ to $\mathrm{Pd}(0)$ by the generated $\mathrm{C}_{60}$ radical anion followed by the complexation between the encapsulated $\mathrm{C}_{60}$ and $\operatorname{Pd}(0)$ in the solution. This serendipitous finding stimulated further investigations of the complexation reaction. According to literature, when pristine $\mathrm{C}_{60}$ and $\mathrm{Pd}(0)$ are reacted in a toluene solution, organometallic $\left[\mathrm{C}_{60} \mathrm{Pd}(0) \mathrm{n}\right] \mathrm{m}$ polymers are formed. ${ }^{[5]}$ In addition, the electronic reduction of the mixture of $\mathrm{C}_{60}$ and $\mathrm{Pd}(I I)$ can also yield the organometallic polymers. ${ }^{[6]}$ The latter example is a similar case to what was observed during $\mathrm{C}_{60}$ radical anion generation as mentioned above. According to these reports, we hypothesized that mere addition of a $\mathrm{Pd}(0)$ source should give the same complexation. Thus, $\mathrm{Pd}(0)(\mathrm{dba})_{2}$ (dba = dibenzylidenaceton) in chloroform was added to $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{~L}_{4}$ in acetonitrile. In the ${ }^{1} \mathrm{H}$ NMR spectrum of the resulting mixture, desymmetrization of $\mathrm{Pd}_{2} \mathrm{~L}^{\mathrm{P}} 4$ was observed, which is likely due to encapsulation of a $\mathrm{C}_{60}$ derivative as discussed in the last chapter (Figure 5.2.1). In the ESI-MS spectrum of the mixture, a prominent signal assignable to the expected $\left[\eta^{2}-\mathrm{C}_{60} \mathrm{Pd}(0) @ \mathrm{Pd}_{2} \mathrm{~L}^{\mathrm{P}}\right]^{4+}$ was observed (Figure 5.2.2). Additionally $\left[\left(\eta^{2}-\mathrm{C} 60 \mathrm{Pd}(0) @ \mathrm{Pd}_{2} \mathrm{~L}^{\mathrm{P}} 4\right)(\mathrm{dba})\right]^{4+}$ was observed as well. This result indicates that $\operatorname{Pd}(0)$ is coordinating other ligands besides encapsulated $\mathrm{C}_{60}$ such as dba or acetonitrile in the solution. An increase of the amount of $\mathrm{Pd}(0)(\mathrm{dba})_{2}$ added into $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{~L}_{4}$ resulted in a formation of $\eta^{2}-\mathrm{C} 60 \mathrm{Pd}(0)_{2}$ inside the coordination cage.

Figure 5.2.3 (a) Synthesis of $\eta^{2}-\mathrm{C}_{60} \mathrm{Pd}(0)_{2} @ \mathrm{Pd}_{2} \mathrm{~L}^{\mathrm{P}} 4$ (b) ${ }^{1} \mathrm{H}$ NMR spectrum ( $\mathrm{CD}_{3} \mathrm{CN}$, $500 \mathrm{MHz}, 298 \mathrm{~K})$ of $\eta^{2}-\mathrm{C}_{60} \mathrm{Pd}(0)_{2} @ \mathrm{Pd}_{2} \mathrm{~L}^{\mathrm{P}} 4$

Addition of 5.0 equivalent of $\mathrm{Pd}(0)(\mathrm{dba})_{2}$ into an acetonitrile solution of $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{~L}^{\mathrm{P}} 4$ under inter atmosphere resulted in a simplified ${ }^{1} \mathrm{H}$ NMR spectrum compared to $\eta^{2-}$ $\mathrm{C}_{60} \mathrm{Pd}(0) @ \mathrm{Pd}_{2} \mathrm{~L}^{\mathrm{P}} 4$ (Figure 5.2.3). New two sets of signals were observed in the ${ }^{1} \mathrm{H}$ NMR spectrum besides residual $\mathrm{C}_{60} \mathrm{Pd}(0) @ \mathrm{Pd}_{2} \mathrm{~L}^{\mathrm{P}}$. This result implies that a species having a higher symmetry was obtained. In the ESI-MS spectrum, $\left[\eta^{2}-\right.$ $\left.\mathrm{C}_{60} \mathrm{Pd}(0)_{2} @ \mathrm{Pd}_{2} \mathrm{~L}_{4}\right]^{4+}$ was found (Figure 5.2.4). Similar to $\eta^{2}-\mathrm{C}_{60} \mathrm{Pd}(0) @ \mathrm{Pd}_{2} \mathrm{~L}^{\mathrm{P}} 4$, a signal assignable to $\eta^{2}-\mathrm{C}_{60} \mathrm{Pd}(0)_{2} @ \mathrm{Pd}_{2} \mathrm{~L}^{\mathrm{P}} 4$ with one dba was also observed. Taking the higher symmetry implication from the ${ }^{1} \mathrm{H}$ NMR spectrum of $\eta^{2}-\mathrm{C} 60 \mathrm{Pd}(0){ }_{2} @ \mathrm{Pd}_{2} \mathrm{~L}^{\mathrm{P}} 4$ into account, the addition of the second $\operatorname{Pd}(0)$ should occur in an antipodal fashion. A preference to the antipodal addition can be seen as a trend both in $\mathrm{C}_{60} \mathrm{Pd}(0)_{n}$ polymers and unimolecular $\mathrm{C}_{60} \mathrm{Pd}(0)$ complexes (Figure 5.2.5). ${ }^{[7,8]}$ For instance, three dimensional $\left[\mathrm{C}_{60} \mathrm{Pd}_{3}\right]_{n}$ organometallic polymers are suggested to have an ordered body-centered-cubic (bcc) $\mathrm{C}_{60}$ units while $\mathrm{Pd}(0)$ atoms are locating in between aligned

Figure 5.2.4 ESI MS spectrum (positive mode) of $\eta^{2}-\mathrm{C} 60 \mathrm{Pd}(0)_{2} @ \mathrm{Pd}_{2} \mathrm{~L}_{4}$

Figure 5.2.5 (a) Schematic structure of 3D $\mathrm{C}_{60 n} \mathrm{Pd}_{3 n}$ organometallic polymers (b) Xray structure of $\eta^{2}-\mathrm{C}_{60} \mathrm{Pd}(0)_{2}$ complex reported by Tanase ${ }^{[8]}$
$\mathrm{C}_{60}$ as depicted in Figure 5.2.5a. ${ }^{[7]}$ As another example, Tanase and co-coworkers have reported an antipodal addition of an oligomeric $\mathrm{Pd}(0)$ complex to $\mathrm{C}_{60}$ (Figure 5.2.5b). ${ }^{[8]}$ Based on the symmetry evidenced by the ${ }^{1} \mathrm{H}$ NMR experiment, the chemical structure of $\mathrm{C}_{60}$, and steric hinderance from the cage, the second addition of $\mathrm{Pd}(0)$ onto the encapsulated $\eta^{2}-\mathrm{C}_{60} \mathrm{Pd}(0)$ under the confinement should be also in an antipodal fashion. The HOMO of the $\eta^{2}-\mathrm{C}_{60} \mathrm{Pd}(0)$ was suggested to be localized on the hexagons
(a)

Highlighted $[6,6]$ bonds
(b)

[6,6] bond at an antipodal position

Figure 5.2 .6 (a) Schegel diagram showing [6,6] bonds of $\mathrm{C}_{60}$ (b) Optimized geometry of $\eta^{2}-\mathrm{C}_{60} \mathrm{Pd}(0)$ with the HOMO calculated at B3LYP/6-31G(d) for C atoms and B3LYP/Lanl2dz for Pd atom in the gas-phase
at the antipodal position by DFT calculations, which further supports the antipodal addition of the second $\operatorname{Pd}(0)$ (Figure 5.2.6). Note that the reaction between $\mathrm{C}_{60}$ and $\mathrm{Pd}(0)(\mathrm{dba})_{3}$ gives organometallic polymers, whereas $\mathrm{Pd}_{2} \mathrm{~L}_{4}$ served as a protecting group to yield the $\mathrm{C}_{60} \mathrm{Pd}(0)_{\mathrm{n}}(\mathrm{n}=1,2)$ complexes inside the cage. However, due to the possible coordination of acetonitrile and the absence of bulky ligands as a cisprotecting group, the obtained $\mathrm{C}_{60} \mathrm{Pd}(0)_{n}$ are rather unstable (Figure 5.2.7). In the ${ }^{1} \mathrm{H}$ NMR spectra measured over time, decomposition of $\eta^{2}-\mathrm{C}_{60} \mathrm{Pd}(0)_{2}$ to $\eta^{2}-\mathrm{C}_{60} \mathrm{Pd}(0)$ as well as $\eta^{2}-\mathrm{C}_{60} \mathrm{Pd}(0)$ to $\mathrm{C}_{60}$ inside the cage was clearly observed. After the experiment, dark precipitates were observed in the NMR tube, which are most likely polymerized $\operatorname{Pd}(0)$. In spite of several attempts to stabilize the obtained $\eta^{2}-\mathrm{C}_{60} \mathrm{Pd}(0)_{\mathrm{n}}(\mathrm{n}=1,2)$ complexes such as through addition of further ligands to stabilize, deoxygenation, dissolving in another solvent after precipitation, none of these strategies was successful. In addition, no further applications have been found yet such as functionalization of confined $\mathrm{C}_{60}$ using the $\eta^{2}-\mathrm{C}_{60} \mathrm{Pd}(0)_{n}$ complexes as an intermediate. A different molecular design for the cage may be required to stabilize the complexes for further investigations. Introduction of bulky substituents on the backbone to protect the coordinated $\mathrm{Pd}(0)$ could be a first step. Furthermore, different ligand designs could be potentially interesting, such as the synthesized thianthrene-based ligand $\mathbf{L}^{\mathbf{S}}$ (

Figure 5.2.8a). The concept of this ligand is to stabilize the obtained $\eta^{2}-\mathrm{C} 60 \mathrm{Pd}(0) \mathrm{n}$ complexes through coordination from the lone pairs on the sulfur atoms to the $\operatorname{Pd}(0)$ atom (Figure 5.2.8b).

Figure 5.2.7 ${ }^{1} \mathrm{H}$ NMR spectra showing the decomposition of $\mathrm{C}_{60} \mathrm{Pd}(0)_{2} @ \mathrm{Pd}_{2} \mathrm{~L}_{4}$ ( $\mathrm{CD}_{3} \mathrm{CN}, 500 \mathrm{MHz}, 298 \mathrm{~K}$ ).

(c)

Figure 5.2.8 (a) Chemical structure of $\mathbf{L}^{\mathbf{s}}$ and its expected self-assembly together with $\mathrm{C}_{60}$ as a guest (b) Simple illustration showing the concept of stabilization through coordination from the sulfur atoms (c) Inversion motion of $\mathbf{L}^{\mathbf{S}}$

Thianthrene presents a similar bent angle to triptycene of approximately $120^{\circ}$ due to the sulfur atoms on the center. Thus, an inner space surrounded by this ligand should be suitable to accommodate $\mathrm{C}_{60}$ similar to $\mathrm{Pd}_{2} \mathrm{LP}_{4}$. The ligand was synthesized following literature procedures. ${ }^{[9]}$ The ligand is poorly soluble in organic solvents preventing spectroscopic analyses. The resulting suspension was soluble in acetonitrile after self-assembly with $[\mathrm{Pd}(\mathrm{II})(\mathrm{MeCN}) 4]\left(\mathrm{BF}_{4}\right)_{2}$ (Figure 5.2.9a). A single set of signals was observed in the ${ }^{1} \mathrm{H}$ NMR spectrum, which could be assigned as $\operatorname{Pd}_{n} \mathbf{L}_{2 n}$ (Figure 5.2.9b). ESI-MS analysis elucidated the chemical composition of the resulting complex to be $\mathrm{Pd}_{3} \mathrm{~L}_{6}$, an unexpected ring-shaped topology (Figure 5.4.17). In fact, a larger hydrodynamic radius of $14.9 \AA$ was obtained by ${ }^{1} \mathrm{H}$ DOSY NMR experiment compared with $\mathrm{Pd}_{2} \mathrm{~L}_{4}$ having a hydrodynamic radius of $11.7 \AA$ due to the higher nuclearity (Figure 5.4.16). On the other hand, cage-to-cage transformation from $\mathrm{Pd}_{3} \mathbf{L}_{6}$ to $\mathrm{Pd}_{2} \mathbf{L}_{4}$ was observed upon encapsulation of $\mathrm{C}_{60}$ in 21:79 ( $\mathrm{Pd}_{3} \mathbf{L}_{6} \mathbf{S}_{6} \mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathbf{L}_{4}$ ) ratio (Figure 5.2.9a and $\mathbf{c}$ ). Characterization was conducted by NMR and ESI MS spectroscopy. Furthermore, a characteristic upfield shift of proton a
(a)

Figure 5.2.9 (a) Self-assembly of $\mathrm{L}^{\mathrm{s}}$ with $\mathrm{Pd}(\mathrm{II})$ and $\mathrm{C}_{60}$ encapsulation (b) ${ }^{1} \mathrm{H}$ NMR spectrum ( $\mathrm{CD}_{3} \mathrm{CN}, 500 \mathrm{MHz}, 298 \mathrm{~K}$ ) of $\mathrm{Pd}_{3} \mathbf{L}_{6}$ and (c) $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathbf{L S}_{4}$
was observed upon $\mathrm{C}_{60}$ encapsulation supporting the assumption that encapsulation of $\mathrm{C}_{60}$ occurs inside the cavity. Despite the uncomplete conversion to $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{~L}_{4}$ even after longer heating with excess $\mathrm{C}_{60}$, synthesis of $\eta^{2}-\mathrm{C}_{60} \mathrm{Pd}(0)_{\mathrm{n}}(\mathrm{n}=1,2)$ complex was carried out by addition of $\mathrm{Pd}(0)(\mathrm{dba})_{2}$. After addition of $\mathrm{Pd}(0)(\mathrm{dba})_{2}$ to an acetonitrile solution of $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathbf{L}_{4}$ in air gives a brownish solution. In the ${ }^{1} \mathrm{H}$ NMR spectrum of the solution, signals belonging to $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{~L}_{4}$ disappeared and a new set of signals indicating an identical symmetry to $\eta^{2}-\mathrm{C}_{60} \mathrm{Pd}(0)_{2} @ \mathrm{Pd}_{2} \mathrm{~L}_{4}$ newly appeared. The formation of $\eta^{2}-\mathrm{C}_{60} \mathrm{Pd}(0)_{2} @ \mathrm{Pd}_{2} \mathrm{~L}_{4}$ was further confirmed by ESI MS analysis. In spite of the lone pairs on the sulfur atoms which were expected to stabilize unstable $\eta^{2}-\mathrm{C}_{60} \mathrm{Pd}(0)_{\mathrm{n}}(\mathrm{n}=1,2)$ within the cage, the stabilization effect could not be observed in solution even in an inert condition (Figure 5.2.10).

Figure 5.2.10 ${ }^{1} \mathrm{H}$ NMR spectra showing the decomposition of $\mathrm{C}_{60} \mathrm{Pd}(0){ }_{2} @ \mathrm{Pd}_{2} \mathrm{~L}_{4}$ ( $\mathrm{CD}_{3} \mathrm{CN}, 500 \mathrm{MHz}, 298 \mathrm{~K}$ ).

Cage-to-cage transformation is facilitated by the template-effect of $\mathrm{C}_{60}$ encapsulation, stabilizing $\mathrm{Pd}_{2} \mathrm{LS}_{4}$ cage. In Ms. Alicia Dullweber's bachelor thesis, synthesis and selfassembly with $\mathrm{Pd}(\mathrm{II})$ of ligand $\mathrm{L}^{\mathrm{A}}$ having an anthracene backbone is described (Figure 5.2.11). ${ }^{[10]}$ It was found that $L^{A}$ forms a ring-shaped $\operatorname{Pd}_{3} L^{A_{6}}$ cage upon self-assembly. It is known that the bite angle of ligands plays a decisive role in the topology of coordination cages. ${ }^{[11,12]}$ For instance, a ligand having a phenanthrene backbone forms $\mathrm{Pd}_{3} \mathrm{~L}_{6}$ assembly upon $\mathrm{Pd}(\mathrm{II})$ addition. ${ }^{[10]}$ The phenanthrene-based ligand has a bite angle of approximately $60^{\circ}$ calculated based on a simple chemical structure. This trend is in a good accordance with the observed behavior of $L^{A}$, having a bite angle of ca. $60^{\circ}$, in self-assembly with Pd (II). On the other hand, ligands having a bite angle of $0^{\circ}$ favorably form $\mathrm{Pd}_{2} \mathrm{~L}_{4}$ topology with square-planar $\mathrm{Pd}(\mathrm{II})$, which should be the case
for $\mathbf{L}^{\mathbf{P}}$ and $\mathbf{L}^{\mathbf{S}}$. However, $\mathbf{L}^{\mathbf{S}}$ gives $\mathrm{Pd}_{3} \mathbf{L}_{6}$ ring as a major species after self-assembly (Figure 5.2.11).

$\mathrm{Pd}_{3} \mathrm{~L}^{\mathrm{A}_{6}}$

No encapsulation
No cage-to-cage transformation

bite angle: $0^{\circ}$

$\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{Ls}_{4}$

bite angle: $0^{\circ}$

Figure 5.2.11 Bite angles of each ligand and the consequence of their assembly with Pd(II)

This should be related to an intrinsic inversion motion of the thianthrene-backbone (
Figure 5.2.8a), having only around $6 \mathrm{kcal} / \mathrm{mol}$ of an energy barrier. ${ }^{[13]}$ Therefore, the inversion motion may average the bite angle of the ligand to be close to $60^{\circ}$ and thus, the resulting topology was $\mathrm{Pd}_{3} \mathbf{L}_{6}$, while encapsulation of $\mathrm{C}_{60}$ inside $\mathrm{Pd}_{2} \mathbf{L}_{4}$ probably suppresses the inversion motion of the ligand to maintain the bite angle to form the lantern-shaped topology.

### 5.3 Conclusion

In conclusion, synthesis of $\mathrm{C}_{60} \mathrm{Pd}(0)_{\mathrm{n}}(\mathrm{n}=1,2)$ could be achieved by preventing polymerization using coordination cages as a supramolecular mask. In addition, synthesis of thianthrene-based ligand $\mathbf{L}^{\mathbf{s}}$ and its self-assembly behavior with $\operatorname{Pd}(I I)$
was investigated. Not only the bite-angle but also the flexibility of the ligand was found to play a role in deciding the topology of the resulting coordination cages. Due to the inversion motion of $\mathbf{L}^{\mathbf{S}}$, coordination cages comprised of the ligand and $\operatorname{Pd}(I I)$ showed cage-to-cage transformation upon encapsulation of $\mathrm{C}_{60}$. Synthesized $\eta^{2}-\mathrm{C}_{60} \mathrm{Pd}(0)_{n}$ ( $\mathrm{n}=1,2$ ) complexes inside both $\mathrm{Pd}_{2} \mathbf{L}_{4}$ and $\mathrm{Pd}_{2} \mathbf{L}_{4}$ are a rather unstable species most likely due to acetonitrile which can act as a competing ligand. None of the attempts, such as cis-protection resulted in an increased stabilization of the system. Further investigations are required for stabilizing the formed complexes.

### 5.4 Appendix

### 5.4.1 Materials and methods

Unless otherwise stated, all chemicals were purchased from commercial sources and used as received. $[\mathrm{Pd}(\mathrm{MeCN}) 4]\left(\mathrm{BF}_{4}\right)_{2}$ and $\mathrm{Pd}(0)(\mathrm{dba})_{2}$ were purchased from Sigma-Aldrich. Corannulene was purchased from TCI.inc. $L^{P}$ was prepared according to literature procedures. ${ }^{[14]}$ Bruker ESI-timsTOF and compact mass spectrometers using Agilent tune mix as calibrant. NMR experiments were performed using Bruker AV 500 Avance NEO, Bruker AV 600 Avance FT-NMR, Bruker Avance III HD 700 MHz spectrometers. ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ signals were referenced to the residual solvent peak: acetonitrile ( $1.94 \mathrm{ppm}, 118.26 \mathrm{ppm}$ ), chloroform ( $7.26 \mathrm{ppm}, 77.16 \mathrm{ppm}$ ). DFT calculation were performed using Gaussian 16, Revision B.01.[15] Hydrodynamic radii of compounds were calculated from Stokes-Einstein equation (eq 1) where $D$ is the diffusion coefficient, $k_{B}$ is the Boltzman constant, $T$ is the temperature, $\eta$ is the viscosity of the solvent, and $r_{H}$ is the hydrodynamic radius of interest. ${ }^{1} \mathrm{H}$ DOSY NMR spectra were recorded with a dstebpgp3s pulse sequence with diffusion delays D20 of 0.08 s and gradient powers P30 of 1200. $T_{1}$ analyses of the corresponding signals in the 1D spectra were performed to obtain the diffusion coefficients $D$ using the STEJSKAL-TANNER-Equation.

### 5.4.2 Synthesis of $\eta^{2}-\mathrm{C} 60 \mathrm{Pd}(0) @ \mathrm{Pd}_{2} \mathrm{~L}^{\mathrm{P}} 4$

Figure 5.4.1 Synthesis of $\eta^{2}-\mathrm{C}_{6} \mathrm{Pd}(0) @ \mathrm{Pd}_{2} \mathrm{~L}_{4}$.

To an acetonitrile solution of $\mathrm{Pd}_{2} \mathrm{LP}_{4}(0.70 \mathrm{mM}, 0.600 \mathrm{~mL}, 0.42 \mu \mathrm{~mol})$, synthesized following the literature, ${ }^{[13]}$ in a NMR tube was added a stock solution of $\operatorname{Pd}(0)(\mathrm{dba})_{2}$ ( $10 \mathrm{mM}, 105 \mu \mathrm{~L}, 2.5$ equiv.) in $\mathrm{CDCl}_{3}$ in the glovebox. After shaking the NMR tube, measurements were carried out.

### 5.4.8 Decomposition of $\eta^{2}-\mathrm{C}_{60} \mathrm{Pd}(0)_{2}$

After preparing $\eta^{2}-\mathrm{C}_{60} \mathrm{Pd}(0)_{2} @ \mathrm{Pd}_{2} \mathbf{L}_{4}$ or $\eta^{2}-\mathrm{C}_{60} \mathrm{Pd}(0)_{2} @ \mathrm{Pd}_{2} \mathrm{~L}^{4}$ in a J. Young NMR tube in the glovebox filled with $\mathrm{N}_{2}$, the sample was left standing in the NMR spectrometer and ${ }^{1} \mathrm{H}$ NMR spectra were measured after a certain period of time to check decomposition of the encapsulated $\eta^{2}-\mathrm{C}_{60} \mathrm{Pd}(0)_{2}$ inside each cages.
$\eta^{2}-\mathrm{C}_{60} \mathrm{Pd}(0)_{2}$ and $\eta^{2}-\mathrm{C}_{60} \mathrm{Pd}(0)$ were found to have a short lifetime within the both cages in solution.

Figure 5.4.31 ${ }^{1} \mathrm{H}$ NMR spectra showing the decomposition of $\mathrm{C}_{6} \mathrm{Pd}(0){ }_{2} @ \mathrm{Pd}_{2} \mathrm{~L}_{4}$ ( $\mathrm{CD}_{3} \mathrm{CN}, 500 \mathrm{MHz}, 298 \mathrm{~K}$ ).

Figure 5.4.32 ${ }^{1} \mathrm{H}$ NMR spectra showing the decomposition of $\mathrm{C}_{60} \mathrm{Pd}(0){ }_{2} @ \mathrm{Pd}_{2} \mathrm{~L}_{4}$ ( $\mathrm{CD}_{3} \mathrm{CN}, 500 \mathrm{MHz}, 298 \mathrm{~K}$ ).

## 6 Guest Uptake and Observation of Topochemical-Like Reaction in between two Nano-Confined Fullerenes

Chemistry in between multiple C6os has been scarcely investigated due to the complexity to precisely align each $\mathrm{C}_{60}$ in appropriate positions. Herein, we report the synthesis of a pill-shaped coordination cage accommodating two fullerenes $\mathrm{C}_{60}$ in close proximity. The molecular design realizes a creation of a nanoscopic space surrounded by the curved $\pi-$ conjugated surface of two C60S. Inside the nanoscopic space, corannulene can be encapsulated with an association constant of a $10^{3}$-order of magnitude resulting in the formation of a charge-transfer complex, while bulk $\mathrm{C}_{60}$ has a neglectable association constant with corannulene. Anthracene and its derivative reacts with one of the encapsulated $\mathrm{C}_{60}$ inside the nanoscopic space yielding a coordination cage accommodating both $\mathrm{C}_{60}$ and its derivative in a quantitative manner. Exchange spectroscopy (EXSY) revealed an existence of repetitive Diels-Alder and retro Diels-Alder reactions, namely topochemical reaction, inside the coordination cage.

### 6.1 Introduction

Figure 6.1.1 $\mathrm{C}_{60}$ array in (a) crystalline state (b) inside hosts (c) hydrogen bonded network and (d) supramolecular polymer (e) schematic illustration of a coordination cage possessing a nanoscopic space in between two $\mathrm{C}_{60}$ s

A countless number of sophisticatedly organized molecules work concertedly to maintain essential functions in livings. ${ }^{[1]}$ What makes them function cooperatively is intermolecular interplay between the molecules. Molecular assemblies gathered by intermolecular forces, supramolecules, often show reversible and stimuli-responsive properties stemming from the dynamic and flexible bonds, which single molecules do not display. ${ }^{[2]}$ Supramolecules show a different behavior from single molecules in a variety of fields such as molecular recognition, catalysis, and material development. ${ }^{[3-}$ 8] In this context, fullerene $\mathrm{C}_{60}$ is of great interest to be investigated since supramolecular arrays including $\mathrm{C}_{60}$ often result in change of the electronic properties of $\mathrm{C}_{60} .^{[9,10]}$ Supramolecular polymerization of $\mathrm{C}_{60}$ derivatives is utilized in material development as well. ${ }^{[11]}$ Furthermore, incorporation of guest molecules between the ordered $\mathrm{C}_{60}$ s can differ the electronic properties. ${ }^{[12]}$ For instance, $\mathrm{C}_{60}$ is known to have a face-centered cubic (fcc) packing structure in the crystal structure. ${ }^{[13]}$ Occupation by alkali metals in the gap between $\mathrm{C}_{60 \text { S }}$ in the fcc packing results in formation of fullerides, salts of $\mathrm{C}_{60}$ radical anions and alkali metals, which show superconductivity at a relatively high temperature. ${ }^{[14]}$ To investigate such molecular arrays of $\mathrm{C}_{60}$, methods to control the arrangement are essential. To align multiple fullerenes, crystallization, encapsulation inside hosts, hydrogen bonds networks, and supramolecular polymerization are often utilized (Figure 6.1.1a-d). ${ }^{[15-17]}$ In addition, incorporation of guests in between arranged pristine $\mathrm{C}_{60 \mathrm{~S}}$ has been also investigated,
albeit most of the cases in the solid-state. ${ }^{[18]}$ On the other hand, to align pristine $\mathrm{C}_{60}$ s in solution is still challenging because of neglectable interactions between spherical $\mathrm{C}_{60}$, Therefore, chemistry in between $\mathrm{C}_{60 \text { S }}$ in solution has not been investigated well, rather never investigated to the best of our knowledge. One of the solutions to arrange pristine $\mathrm{C}_{60}$ in an ordered manner in solution is encapsulation of $\mathrm{C}_{60}$ inside hosts. ${ }^{19-}$ ${ }^{23]}$ A few examples of hosts which can encapsulate multiple $\mathrm{C}_{60 \text { S }}$ within their cavities have been reported, however, deeper investigations into their chemistry, e.g. hostguest chemistry, in between the encapsulated $\mathrm{C}_{60}$ s are still missing. Thus, construction of such molecular systems and investigation of the chemistry in between multiple $\mathrm{C}_{60}$ s will help build a fundamental basic knowledge for further development of futuristic materials.

Herein, we report a synthesis of a pill-shaped coordination cage dimer encapsulating two $\mathrm{C}_{60}$ s within each cavity. Thanks to the nanoscopic space surrounded by two $\mathrm{C}_{60}$ S, host-guest chemistry in between two $\mathrm{C}_{60}$ s could be investigated. We have employed a convergent method to construct such a pill-shaped coordination cage having an appropriately sized nano-space for accommodation of single molecule in between two C60S (Figure 6.1.1e).

### 6.2 Results and discussion

Figure 6.2.1 Synthesis of $\mathrm{Pd}_{2} \mathrm{~L}_{3}(\mathrm{MeCN})_{2}$ and $\left(\mathrm{C}_{60}\right)_{2} @ \mathrm{Pd}_{4} \mathrm{~L}_{6}(\mathrm{Nap})_{2}$ (b) ESI-MS spectrum (positive) of $\left(\mathrm{C}_{60}\right)_{2} @ \mathrm{Pd}_{4} \mathrm{~L}_{6}{ }_{6}(\mathrm{Nap})_{2}(\mathrm{c}){ }^{1} \mathrm{H}$ NMR spectrum $\left(\mathrm{CD}_{3} \mathrm{CN}, 500 \mathrm{MHz}\right.$, 298 K ) of $\mathrm{L}^{\mathrm{Q}}$ (d) $\mathrm{Pd}_{2} \mathrm{~L}_{3}(\mathrm{MeCN})_{2}(0.70 \mathrm{mM})$ (e) $\mathrm{Pd}_{4} \mathrm{~L}^{\mathrm{Q}_{6}}(\mathrm{Nap})_{2}(0.34 \mathrm{mM})$ and (f) ( $\left.\mathrm{C}_{60}\right)_{2} @ \mathrm{Pd}_{4} \mathrm{~L}^{\mathrm{Q}}{ }_{6}(\mathrm{Nap})_{2}(0.34 \mathrm{mM})$

The triptycene-based ligand $\mathbf{L}^{\mathbf{Q}}$ was synthesized in a moderate yield following the literature (Figure 6.2.1a,c and Figure 6.4.1). ${ }^{[23-25]}$ Triptycene is known to have attractive interactions with $\mathrm{C}_{60}$ through convex-concave principle. ${ }^{[26]}$ We have previously reported a synthesis of a bowl-shaped coordination cage via coordination sphere engineering. ${ }^{[23,27,28]}$ Following the literature, $\mathrm{Pd}_{2} \mathrm{LQ}_{3}(\mathrm{MeCN})_{2}$ was synthesized via self-assembly by mixing $\mathrm{L}^{\mathrm{Q}}$ and 0.67 equivalent of $\left[\mathrm{Pd}(\mathrm{II})(\mathrm{MeCN})_{4}\right]\left(\mathrm{BF}_{4}\right)_{2}$ in $\mathrm{CD}_{3} \mathrm{CN}$
at ambient temperature (Figure 6.2.1b). ${ }^{[23]}$ In the ${ }^{1} \mathrm{H}$ NMR spectrum of $\mathrm{Pd}_{2} \mathrm{~L}_{3}(\mathrm{MeCN})_{2}$, most of the protons of the quinoline donor-sites showed downfield shifts upon coordination, which is a ubiquitous phenomenon found in coordination cages due to electron density transfer from ligands to metal centers. ${ }^{[23]}$ In addition, two and three sets of signals were observed in 2:1 and 1:1:1 ratio for the quinoline donorsites and the backbone of the ligand respectively, suggesting formation of the bowlshaped structure (Figure 6.2.1d). Coordination of the fourth ligand is prohibited owing to the steric bulk around the Pd (II) centers. Recently, we have reported that addition of a terephtalate-linker yields a pill-shaped dimer by bridging two bowl-shaped coordination cages. ${ }^{[23]}$ However, no host-guest capability of the pill-shaped coordination cage was found, most probably due to the too small space between the encapsulated $\mathrm{C}_{60}$ s. Therefore, 2,6-naphthalenedicarboxylate (Nap) was employed as a linker to expand the distance in between two $\mathrm{C}_{60}$ s. The pill-shaped coordination cage, $\mathrm{Pd}_{4} \mathrm{~L}_{6}(\mathrm{Nap})_{2}$, was obtained after dropwise addition of an aqueous solution of Nap as a sodium salt into an acetonitrile solution of $\mathrm{Pd}_{2} \mathrm{LQ}_{3}(\mathrm{MeCN})_{2}$ while stirring (Figure 6.2.1e). Encapsulation of $\mathrm{C}_{60}$ was conducted by dispersing excess amount of $\mathrm{C}_{60}$-solid into the acetonitrile solution of $\mathrm{Pd}_{4} \mathrm{~L}^{\mathrm{Q}_{6}}(\mathrm{Nap})_{2}$ at room temperature for 24 h . The colorless solution turned purple which is the characteristic color of $\mathrm{C}_{60}$, although $\mathrm{C}_{60}$ is insoluble in acetonitrile. Formation of ( $\left.\mathrm{C}_{60}\right)_{2} @ \mathrm{Pd}_{4} \mathbf{L}^{\mathrm{Q}_{6}}(\mathrm{Nap})_{2}$ was confirmed by electrospray ionization mass spectrometry (ESI-MS) and NMR analysis (Figure 6.2.1b and $\mathbf{f}$ ). The hydrodynamic radius of $\left(\mathrm{C}_{60}\right)_{2} @ \mathrm{Pd}_{4} \mathbf{L}^{\mathrm{Q}_{6}}(\mathrm{Nap})_{2}$ was determined to be $17.0 \AA$ by diffusion ordered spectroscopy (DOSY) which is larger than $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{~L}_{3}(\mathrm{MeCN})_{2}$ (Figure 6.4.28 and Figure 6.4.68).
The structure of ( $\left.\mathrm{C}_{60}\right)_{2} @ \mathrm{Pd}_{4} \mathrm{~L}_{6} \mathrm{Q}_{(\mathrm{Nap}) 2}$ was unambiguously revealed by single crystal X-ray structure analysis using synchrotron radiation (Figure 6.2.2a-b). ${ }^{[29]}$ Block-like single crystals suitable for crystallographic analysis was obtained by slow diffusion of benzene into an acetonitrile solution of $\left(\mathrm{C}_{60}\right)_{2} @ \mathrm{Pd}_{4} \mathrm{~L}^{\mathrm{Q}_{6}}(\mathrm{Nap})_{2}$. Two independent halves of the dimer were found in the unit cell (Figure 6.4.45 and Figure 6.4.46). Only one of the dimers is showcased in Figure 6.2.2. The distance between the centers of mass of the encapsulated $\mathrm{C}_{60}$ s inside each dimer was determined to be $13.0 \AA$ and $12.8 \AA$ respectively. Subtraction of the diameter of $\mathrm{C}_{60}$ of $7 \AA$ gives $6 \AA$ and $5.8 \AA$ of the distance of the surface of each confined $\mathrm{C}_{60} \mathrm{~S}$, which should be large enough to accommodate a single guest molecule via $\pi-\pi$ interactions(Figure 6.2.2c). The variation of the distances implies the flexibility of the molecular system even in the

Figure 6.2.2. Single crystal X-ray structure of one of $\left(\mathrm{C}_{60}\right)_{2} @ \mathrm{Pd}_{4} 1_{6}(\mathrm{Nap})_{2}$ co-exist (a) front view (b) top view (c) distance between the centers of mass of confined $\mathrm{C}_{60}$ g given the diameter of $\mathrm{C}_{60}$ is $7 \AA$. Hydrogen atoms, solvent molecules, and counter anions were omitted for clarity. Color legends: C : grey N : blue O : red Pd : orange $\mathrm{C}_{60}$ : sky blue
solid-state. Next, host-guest chemistry inside the nanoscopic space surrounded by two $\mathrm{C}_{60}$ s was investigated (Figure 6.2.3a).

Corannulene, known as a substructure of $\mathrm{C}_{60}$, was employed as a suitable guest molecule. Thanks to the warped structure, corannulene has a moderately good solubility in acetonitrile, which is an important criterion for fine analyses. Besides, encapsulation of corannulene can be a good experiment to see an effect from the well alignment of $\mathrm{C}_{60 \mathrm{~S}}$ in the cage because corannulene is known to have a neglectable association constant with pristine $\mathrm{C}_{60}$ in solution. ${ }^{[30]}$ To determine a binding constant of corannulene inside the nano-space, a titration experiment was carried out using ${ }^{1} \mathrm{H}$ NMR and UV-Vis absorption spectroscopy. In addition to the change in the ${ }^{1} \mathrm{H}$ NMR chemical shifts, the emergence of an absorption band around 450 nm was also observed over the course of the titration, which is indicating of a formation of a chargetransfer complex between the encapsulated $\mathrm{C}_{60}$ s and the bound corannulene (Figure 6.2.3c). ${ }^{[30]}$ Among the protons of the quinoline coordination-sites, protons e/e' which are supposed to be pointing towards the encapsulated $\mathrm{C}_{60}$ gave the large chemical shifts during the titration experiment, which indicates electronic perturbation on the confined $\mathrm{C}_{60 \text { S }}$ by the charge-transfer complex formation (Figure 6.2.3d). The binding constant, $K_{a}$, was determined to be $4.4 \pm 0.1 \times 10^{3} \mathrm{M}^{-1}$ by fitting the data using BindFit

Figure 6.2.3 (a) Encapsulation of Corannulene into $\left(\mathrm{C}_{60}\right)_{2} @ \mathrm{Pd}_{4} \mathrm{~L}_{6}(\mathrm{Nap})_{2}(\mathrm{~b})$ ESI-MS spectrum (positive) of $1: 1$ molecular complex of corannulene and $\left(\mathrm{C}_{60}\right)_{2} @ \mathrm{Pd}_{4} \mathrm{~L}_{6}{ }_{6}(\mathrm{Nap})_{2}$ (c) UV-vis absorption spectrum of $\left(\mathrm{C}_{60}\right)_{2} @ \mathrm{Pd}_{4} \mathbf{L}_{6}{ }_{6}(\mathrm{Nap})_{2}$ (acetonitrile, $298 \mathrm{~K}, 0.34 \mathrm{mM}$ ) over corannulene titration (d) ${ }^{1} \mathrm{H}$ NMR spectrum ( 500 $\left.\mathrm{MHz}, \mathrm{CD}_{3} \mathrm{CN}, 298 \mathrm{~K}\right)$ of $\left(\mathrm{C}_{60}\right)_{2} @ \mathrm{Pd}_{4} \mathrm{~L}_{6}(\mathrm{Nap})_{2}$ with and without corannulene
(Figure 6.4.53 \& Table 6.4.2). ${ }^{[31]}$ Furthermore, the formation of the $1: 1$ complex was also confirmed by ESI-MS (Figure 6.2.3b) The obtained $K_{a}$ is comparable to other hosts showing binding capability toward corannulene. ${ }^{[32,33]}$ Furthermore, considering that both naked $\mathrm{C}_{60}$ and the confined $\mathrm{C}_{60}$ inside $\mathrm{Pd}_{2} \mathrm{~L}_{3}(\mathrm{MeCN})_{2}$ showed a neglectable association behavior with corannulene, the association constant was dramatically improved by having another $\mathrm{C}_{60}$ in close proximity. This observation suggests that the curved surface of $\mathrm{C}_{60}$ can be a building block to create a host-molecule despite of the scarce host-guest capability itself alone.

 $\mathrm{C}_{60} \mathrm{DMA} \cdot \mathrm{C}_{60} @ \mathrm{Pd}_{4} \mathrm{~L}^{\mathrm{Q}_{6}}(\mathrm{Nap})_{2}(0.33 \mathrm{mM})$

We further explored the host-guest chemistry inside the nanoscopic space using anthracene (Figure 6.2.4a) In the course of the experiment, we found that anthracene shows an intriguing encapsulation behavior. Over the titration experiment of anthracene into an acetonitrile solution of $\left(\mathrm{C}_{60}\right)_{2} @ \mathrm{Pd}_{4} 1_{6}(\mathrm{Nap})_{2}$, two sets of signals newly arose. We assumed that the entrapped anthracene reacted with one of the encapsulated $\mathrm{C}_{60}$ s and gave a Diels-Alder adduct inside the cage considering the symmetry. To prove the hypothesis, 1.0 equivalent of anthracene was added into acetonitrile solution of $\left(\mathrm{C}_{60}\right)_{2} @ \mathrm{Pd}_{4} \mathbf{1}_{6}(\mathrm{Nap})_{2}$ and the mixture was let stand in the dark at ambient temperature for 4 days. A clean conversion from (C60)2@Pd416(Nap)2 to the new species was observed (Figure 6.2.4b-c and Figure 6.4.31). In the ${ }^{1} \mathrm{H}$ NMR spectrum, two sets of signals appeared stemming from the heteromultimeric encapsulation. ESI-MS analysis revealed the formation of $\mathrm{C}_{60} a n t \cdot \mathrm{C}_{60} @ \mathrm{Pd}_{4} \mathbf{1}_{6}(\mathrm{Nap})_{2}$ as we assumed (Figure 6.4.36). Note that this is the first example of the rational synthesis of host-guest complex encapsulating two different fullerenes to the best of our
knowledge. Diels-Alder reaction in between two C60s has been studied theoretically by Podewitz et al., however, most of molecular systems could not provide them with an appropriate model to explore experimentally. ${ }^{[34]}$ In general, Diels-Alder reaction of $\mathrm{C}_{60}$ and anthracene yields an equilibrium together with multi-adducts formation. Thus, quantitative formation of $\mathrm{C}_{60}$ ant is challenging. However, this was not the case inside (C60) ${ }_{2} @ P_{4} 1_{6}(\mathrm{Nap})_{2}$. According to the theoretical study, it is indicated that an activation Gibbs free energy ( $\Delta G^{\ddagger}$ ) barrier for a Diels-Alder reaction with anthracene should be lowered thanks to the neighboring $\mathrm{C}_{60}{ }^{[34]}$ In addition, the resulting $\mathrm{C}_{60}$ ant is indicated to be stabilized thanks to the neighboring $\mathrm{C}_{60}$ probably via convex-concave interactions. Thanks to those effects, the possibility of a topochemical reaction is implied. ${ }^{[34]}$ Stimulated by that theoretical study, we investigated the topochemical-like reaction within the soluble dimer cage. In fact, a transfer of anthracene from $\mathrm{C}_{60}$ ant to neighboring $\mathrm{C}_{60}$ has been reported using a variety of anthracene derivatives, e.g., 9,10-dimethylanthracene (DMA) in the solid-state. ${ }^{[35]}$ To deeply investigate the reaction, we have performed kinetic studies with our system in solution (Figure 6.4.57 and Figure 6.4.58). As a result, the activation Gibbs free energy barrier $\Delta G^{\ddagger}$ was determined to be $79 \mathrm{~kJ} / \mathrm{mol}$ at 298 K which is lower than the one for the Diels-Alder reaction between anthracene and naked $\mathrm{C}_{60}$ in a toluene solution by $14 \mathrm{~kJ} / \mathrm{mol}$ (Figure 6.4.58). ${ }^{[36]}$ Taking it into account that kinetics in Diels-Alder reactions are, in general, independent from solvents, the lower $\Delta G^{\ddagger}$ should be attributed to the effect of the neighboring $\mathrm{C}_{60}$. The neighboring $\mathrm{C}_{60}$ should stabilize the transition-state via $\pi-\pi$ interactions between the slightly bent anthracene. In fact, $\mathrm{C}_{60}$ encapsulated inside $\mathrm{Pd}_{2} \mathrm{~L}_{3}(\mathrm{MeCN})_{2}$ did not undergo Diels-Alder reaction with anthracene to yield $\mathrm{C}_{60}$ ant $@ \mathrm{Pd}_{2} \mathrm{~L}_{3}(\mathrm{MeCN})_{2}$ even after seven days at room temperature. Next, we tackled to elucidate if a topochemical reaction takes place within the coordination cage. For this purpose, more reactive 9,10-dimethylanthracene (DMA) was employed as a diene. DMA is notorious for a fast retro-Diels-Alder reaction and a bis-adduct formation even at room temperature. ${ }^{[37,38]}$ Mixing a stoichiometric amount of DMA and $\left(\mathrm{C}_{60}\right)_{2} @ \mathrm{Pd}_{4} \mathrm{~L}^{\mathrm{Q}_{6}}(\mathrm{Nap})_{2}$ immediately yielded $\left.\mathrm{C}_{60} \mathrm{DMA} \cdot \mathrm{C}_{60} @ \mathrm{Pd}_{4} \mathrm{~L}_{6} \mathrm{Q}_{6} \mathrm{Nap}\right)_{2}$ in a quantitative manner despite the possibility of falling apart again by a retro Diels-Alder reaction (Figure 6.2.4d and Figure 6.4.37).

(b)
(c) $E$

Figure 6.2.5 (a) Schematic illustration of the topochemical reaction within the cage (b) EXSY (dotted line) and NOESY (solid line) correlations (c) An energy diagram explaining encapsulation of anthracene/DMA between the encapsulated $\mathrm{C}_{60}$ S and the following topochemical reaction

To elucidate the dynamic behavior of the $\mathrm{C}_{60}-\mathrm{DMA}$ adduct within the cage, EXSY experiments were performed at various mixing times. If there is a guest-exchange related to the expected topochemical reaction within the cage, pairs of protons of each cage halve should show EXSY correlation (Figure 6.2.5a). The signal pairs (a-a*), (a'$a^{* \prime}$ ), and ( $f^{\prime}-f^{* \prime}$ ) are suitable pairs owing to less overlapping with other signals. When the EXSY spectrum was measured at $57.8^{\circ} \mathrm{C}$ with 1 s mixing time by Prof. Hiller, all the three pairs showed EXSY correlations (Figure 6.2.5b and Figure 6.4.77). Since the proton $a / a^{*}$ does not have EXSY correlation with one of $a^{\prime} / a^{* \prime}$, the possibility of ligand exchange can be excluded. Note that, the retro-Diels-Alder reaction was observed in the case of $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{~L}_{3}(\mathrm{MeCN})_{2}$ upon elevating the temperature (Figure 6.4.73). These results strongly support our hypothesis that the sequential retro-Diels-Alder/Diels-Alder reactions take place in between two $\mathrm{C}_{60}$ inside the cage. The exchange rate was estimated to be 0.45-1.52 $\mathrm{s}^{-1}$ from the EXSY experiment. The activation Gibbs free energy barrier could be calculated from these rates to be $81.7 \pm$ $1.5 \mathrm{~kJ} / \mathrm{mol}$ at the experiment temperature. Considering that the equilibrium constant
of the Diels-Alder reaction between naked $\mathrm{C}_{60}$ and DMA is $110 \mathrm{M}^{-1}$ at 325 K resulting in $\Delta G=-12.7 \mathrm{~kJ} / \mathrm{mol},{ }^{[38]}$ it can be concluded that the neighboring $\mathrm{C}_{60}$ stabilizes $\mathrm{C}_{60} \mathrm{DMA}$ adduct inside $\mathrm{Pd}_{4} \mathrm{~L}^{\mathrm{Q}_{6}}(\mathrm{Nap})_{2}$. This suggests that the second $\mathrm{C}_{60}$ in close proximity stabilizes both transition state and product probably via convex-concave interactions as suggested theoretically. ${ }^{[34]}$ To further support this conclusion, the following control experiments were carried out. In the presence of excess amount of corannulene, $\mathrm{C}_{60} \mathrm{DMA} \cdot \mathrm{C}_{60} @ \mathrm{Pd}_{4} \mathrm{~L}_{6}{ }_{6}(\mathrm{Nap})_{2}$ was let stand either in the dark or under the ambient light in the air for 3 days. If there is such a topochemical reaction within the cage, corannulene having the higher association constant (anthracene: ca. $199 \mathrm{M}^{-1}$ ) should replace DMA in an intermediate state (Figure 6.4.56 and Table 6.4.3). A binding constant towards DMA could not be obtained due to the instant Diels-Alder reaction. As a result, only slight guest exchange was observed from the sample left in the dark while full guest exchange was observed together with the hetero-Diels-Alder product of DMA and singlet oxygen from the one left under the light (Figure 6.4.79). These results implied that the trapped DMA between two $\mathrm{C}_{60}$ s rather undergoes the Diels-Alder reaction with one of $\mathrm{C}_{60}$ s than being expelled from the nanoscopic space. An energy diagram based on the observations is summarized in Figure 6.2.5c. The DFT calculations suggest that the activation energy barrier for escape of the entrapped anthracene is higher than the one for the Diels-Alder reaction (Figure 6.2.5c and Figure 6.4.80). The entrapped DMA should keep staying in between two $\mathrm{C}_{60}$ S and proceed the topochemical reaction within the coordination cage.

### 6.3 Conclusion

In this report, the synthesis of a pill-shaped coordination cage having a nanoscopic space suitable to encapsulate a guest molecule in between two $\mathrm{C}_{60}$ is reported. The association constant between corannulene and $\mathrm{C}_{60}$ was found to be dramatically increased due to the nano-confinement effects. Encapsulation of anthracene in the space lead to the first example of heteromultimeric encapsulation of two different fullerenes. The Gibbs activation free energy barrier for the Diels-Alder reaction between $\mathrm{C}_{60}$ and anthracene was lower than the one of naked $\mathrm{C}_{60}$ due to the close proximity to the other $\mathrm{C}_{60}$. A quantitative formation of the heteromultimeric encapsulating cage was achieved even with 9,10-dimethylanthracene known to show
a retro-Diels-Alder reaction at ambient temperature, most likely due to the stabilization effect by the neighboring $\mathrm{C}_{60}$. A clue of a topochemical-like reaction inside the cage was observed by EXSY experiments. The author believe that this result has paved the way toward a new concept of supramolecular chemistry.

### 6.4 Appendix

### 6.4.1 Materials and methods

Unless otherwise stated, all chemicals were purchased from commercial sources and used as received. $[\mathrm{Pd}(\mathrm{MeCN}) 4]\left(\mathrm{BF}_{4}\right)_{2}$ and 6 -aminoquinoline purchased from Sigma-Aldrich. Corannulene was purchased from TCI.inc. L $^{Q}$ was prepared according to literature procedures. ${ }^{[23,25]}$ Electrospray ionization (ESI) mass spectra were recorded using Bruker ESI-timsTOF and compact mass spectrometers using Agilent tune mix as calibrant. NMR experiments were performed using Bruker AV 500 Avance NEO, Bruker AV 600 Avance FT-NMR and Bruker AV 700 Avance FTNMR spectrometers. ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ signals were referenced to the residual solvent peak: acetonitrile (1.94 ppm,118.26 ppm), chloroform (7.26 ppm, 77.16 ppm ). DFT calculation were performed using Gaussian Gaussian 16, Revision B.01. ${ }^{[2]}$ Hydrodynamic radii of compounds were calculated from Stokes-Einstein equation (eq 1 ) where $D$ is a diffusion coefficient, $k_{B}$ is Boltzman constant, $T$ is a temperature, $\eta$ is a viscosity of the solvent, and $r_{H}$ is a hydrodynamic radius of interest. ${ }^{1} \mathrm{H}$ DOSY NMR spectra were recorded with a dstebpgp3s pulse sequence with diffusion delays D20 of 0.08 s and gradient powers P30 of 1200. $T_{1}$ analyses of the corresponding signals in the 1D spectra were performed to obtain the diffusion coefficients $D$ using the STEJSKAL-TANNER-Equation.

### 6.4.3 X-ray Crystallography

$\left(\mathrm{C}_{60}\right)_{2} @ \mathrm{Pd}_{4} \mathrm{~L}_{6}{ }_{6}(\mathrm{Nap})_{2}$ were studied using single-crystal X-ray diffraction. Due to very thin plate or needle-shaped crystals, the analysis was hampered by the limited scattering power of the samples not allowing to reach the desired (sub-)atomic resolution using our modern micro-focused X -ray $\mathrm{Cu}-\mathrm{K}_{\alpha}$ in-house source. Gaining detailed structural insight thus required cryogenic crystal handling and highly brilliant synchrotron radiation. Hence, diffraction data of was collected during at macromolecular synchrotron beamline P11, PETRA III, DESY. ${ }^{[29]}$ Counterion and solvent flexibility required carefully adapted macromolecular refinement protocols employing geometrical restraint dictionaries, similarity restraints and restraints for anisotropic displacement parameters (ADPs). The crystal structures were refined and deposited on the CCDC database by Dr. Julian J. Holstein. In addition, the following detail description of the refinement was contributed by Dr. Julian J. Holstein.

### 6.4.3.1 $\left(\mathrm{C}_{60}\right)_{2} @ \mathrm{Pd}_{4} \mathrm{~L}^{\mathrm{a}_{6}}(\mathrm{Nap})_{2}$

Figure 6.4.44 X-ray structure of $\left(\mathrm{C}_{60}\right)_{2} @ \mathrm{Pd}_{4} \mathrm{~L}_{6}(\mathrm{Nap})_{2}$. One of two independent supramolecular assemblies in the asymmetric unit is shown. Co-crystallised tetrafluoroborate counter anions, benzene and acetonitrile solvent molecules as well as hydrogen atoms are omitted for clarity. Color scheme: C (gray), N (blue), O (red), and Pd (orange)

Single crystals were grown by slow diffusion of benzene into a solution of $\left(\mathrm{C}_{60}\right)_{2} @ \mathrm{Pd}_{4} \mathrm{~L}_{6} \mathbf{Q}_{6}(\mathrm{Nap})_{2}$ in acetonitrile. A single crystal of $\left(\mathrm{C}_{60}\right)_{2} @ \mathrm{Pd}_{4} \mathbf{L}_{6}(\mathrm{Nap})_{2}$ in mother liquor was pipetted onto a glass slide containing NVH oil. Six crystals were quickly mounted onto nylon loops and immediately flash cooled in liquid nitrogen, to prevent cracking of the crystals due to loss of highly volatile organic solvents. Crystals were stored at cryogenic temperature in dry shippers, in which they were safely transported to macromolecular beamline P11 at Petra III,[29] DESY, Germany. A wavelength of $\lambda=1.03320 \AA$ was chosen using a liquid $N_{2}$ cooled double crystal monochromator. Single crystal X-ray diffraction data was collected at 100(2) K on a single axis goniometer, equipped with an Oxford Cryostream 800 open flow cooling device and an Eiger 2x 16M detector. 3600 diffraction images were collected in a $360^{\circ}$ $\varphi$ sweep at a detector distance of $154 \mathrm{~mm}, 100 \%$ filter transmission, $0.1^{\circ}$ step width and 30 ms (milliseconds) exposure time per image. Out of six crystals prepared only
one crystal yielded diffraction data of sufficient quality for indexing and structure solution, while the other five suffered from solvent loss resulting in a collapse of the crystal lattice, despite careful and quick crystal picking. Data integration and reduction were undertaken using XDS. ${ }^{[39]}$ The structure was solved by intrinsic phasing/direct methods using SHELXT ${ }^{[40]}$ and refined with SHELXL ${ }^{[41]}$ using 22 CPU cores for fullmatrix least-squares routines on $F^{2}$ and ShelXIe ${ }^{[42]}$ as a graphical user interface and the DSR program plugin was employed for modeling. ${ }^{[43,44]]}$ The asymmetric unit contains two symmetry independent halves of the pill shaped supramolecular assembly ( $\left.\mathrm{C}_{60}\right)_{2} @ \mathrm{Pd}_{4} \mathrm{~L}_{6}(\mathrm{Nap})_{2}$. One of the four co-crystallized tetrafluoroborate anions was modelled with two discrete positions refining their occupancy factor to 52:48 using a free variable. Co crystallized benzene molecules were modelled on twelve position, six of which only $50 \%$ occupied and one Acetonitrile molecule was modelled. Due to extremely small crystal size, disorder and poor crystal quality required stereochemical restraints to be employed for ensuring a sensible geometry of the organic part of the structure.

Stereochemical restraints for the ligands L $^{\mathbf{Q}}$ (residue class TRQ), bridging NAP ligands (residue class NAP) and co-crystallized benzene solvent molecules (residue class BEN) and acetonitrile molecule (residue class ACN) were generated by the GRADE program using the GRADE Web Server (http://grade.globalphasing.org) and applied in the refinement. A GRADE dictionary for SHELXL contains target values and standard deviations for 1,2-distances (DFIX) and 1,3-distances (DANG), as well as restraints for planar groups (FLAT). All displacements for non-hydrogen atoms were refined anisotropically. The refinement of ADPs for carbon, nitrogen and oxygen atoms was enabled by a combination of similarity restraints (SIMU) and rigid bond restraints (RIGU). ${ }^{[45]}$ The contribution of the electron density from disordered counterions and solvent molecules, which could not be modeled with discrete atomic positions, were handled using the SQUEEZE ${ }^{[46]}$ routine in PLATON. ${ }^{[47]}$ The solvent mask file (.fab) computed by PLATON were included in the SHELXL refinement via the ABIN instruction leaving the measured intensities untouched.

Figure 6.4.45 Unit cell of $\left(\mathrm{C}_{60}\right)_{2} @ \mathrm{Pd}_{4} \mathrm{~L}_{6}(\mathrm{Nap})_{2}$. Two halves of the dimer are filled in the unit cell. Hydrogen atoms are omitted for clarity. Color scheme: C (gray), $\mathrm{C}_{60}$ (skyblue), N (blue), O (red), and Pd (orange)

Figure 6.4.46 Single crystals X-ray structure of dimers co-exist (a)
 N (blue), O (red), and Pd (orange)

Two independent halves of $\left(\mathrm{C}_{60}\right)_{2} @ \mathrm{Pd}_{2} \mathrm{~L}^{\mathrm{Q}_{6}}(\mathrm{Nap})_{2}$ were found in the asymmetric unit cell. The distances of the center of mass of the encapsulated $\mathrm{C}_{60}$ s within each dimer and the values subtracted by the diameter of $\mathrm{C}_{60}$ are listed in Table S1 below. The deviation of the distance implies the flexibility of the nanoscopic space inside the dimer.

| Dimer | Distance $[\AA \AA]$ | COM-C60 $[\AA ̊]$ |
| :---: | :---: | :---: |
| 1 | 12.8 | 5.8 |
| 2 | 13.0 | 6.0 |

### 6.4.4.1.3 Optical properties

To an acetonitrile solution of $\left(\mathrm{C}_{60}\right)_{2} @ \mathrm{Pd}_{4} \mathrm{~L}_{6}(\mathrm{Nap})_{2}, 9.0$ equivalent of corannulene was added. Immediately after addition, the solution color changed from purple to yellow due to the charge transfer complex formation between the encapsulated $\mathrm{C}_{60}$ and the bound corannulene. The UV-Vis absorption spectra of the charge transfer complex were measured in acetonitrile ( $298 \mathrm{~K}, 0.34 \mathrm{mM}, I=1.0 \mathrm{~cm}$ ). The intensity of the absorbance increased around 450 nm , which is in good accordance with the literature. ${ }^{[30]}$

Figure 6.4.52 UV-Vis absorption spectra of yellow: Cor•( $\left.\mathrm{C}_{60}\right)_{2} @ \mathrm{Pd}_{4} \mathrm{~L}^{\mathrm{Q}_{6}}(\mathrm{Nap})_{2}(0.30$ $\mathrm{mM}, I=1 \mathrm{~cm}, 298 \mathrm{~K}, \mathrm{CD}_{3} \mathrm{CN}$ ), purple: ( $\left.\mathrm{C}_{60}\right)_{2} @ \mathrm{Pd}_{4} \mathrm{~L}_{6}{ }_{6}(\mathrm{Nap})_{2}(0.34 \mathrm{mM}, I=1 \mathrm{~cm}, 298$ $\left.\mathrm{K}, \mathrm{CD}_{3} \mathrm{CN}\right)$, black: corannulene ( $1 \mu \mathrm{M}, I=1 \mathrm{~cm}, 298 \mathrm{~K}, \mathrm{CD}_{3} \mathrm{CN}$ )

### 6.4.4.1.4 Determination of binding constant

From the titration NMR experiment using ( $\left.\mathrm{C}_{60}\right)_{2} @ \mathrm{Pd}_{4} \mathrm{~L}^{\mathrm{Q}_{6}(\mathrm{Nap})_{2}}$ as a host and corannulene as a guest, the binding constant was determined using BindFit ver.0.5. ${ }^{[48]}$ The signals of proton $h$, which shows no overlap with other signals, was adopted for the analysis. The plot is shown in Figure 6.4.53 and the outcome of the fitting is summarized in Table 6.4.2.

### 6.4.5 Detail studies on Diels-Alder reaction

### 6.4.5.1 Kinetic analysis

The reaction rate of the Diels-Alder reaction of the encapsulated $\mathrm{C}_{60}$ inside the cage with anthracene was determined by ${ }^{1} \mathrm{H}$ NMR analysis at deferent temperatures (298 $\mathrm{K}, 303 \mathrm{~K}, 308 \mathrm{~K}$ ). The analysis is limited in this range due to precipitation at higher temperature than this range. To an acetonitrile solution of ( $\left.\mathrm{C}_{60}\right)_{2} @ \mathrm{Pd}_{4} \mathrm{~L}_{6}(\mathrm{Nap})_{2}(0.34$ $\mathrm{mM}, 0.600 \mathrm{~mL}, 0.20 \mu \mathrm{~mol}$ ) in an NMR tube, a certain amount of an acetonitrile solution of anthracene was added in the dark. The NMR tube was shaken and let stand for a certain time at a certain temperature till to be measured. The reaction was analyzed as a second order reaction following the equation below. The obtained $k$ values at each temperature were plotted in an Eyring plot and the activation energy barrier was estimated. The experiment was repeated three times.

$$
\begin{aligned}
& \ln \left(\frac{[B]\left[A_{0}\right]}{[A]\left[B_{0}\right]}\right)=\left(\left[B_{0}\right]-\left[A_{0}\right]\right) k t
\end{aligned}
$$

Figure 6.4.57 Plots over the Diels-Alder reaction as second order reactions measured at variable temperatures

Figure 6.4.58 Eyring plot of the Diels-Alder reaction

An activation enthalpy $\Delta H^{\ddagger}$ was estimated from the value of the slope to be $48 \mathrm{~kJ} / \mathrm{mol}$. An activation entropy $\Delta S^{\ddagger}$ was calculated to be $-104 \mathrm{~J} / \mathrm{mol}$ from the intercept. An activation Gibbs free energy $\Delta G^{\ddagger}$ at 298 K was calculated to be $79 \mathrm{~kJ} / \mathrm{mol}$ from the aforementioned values using the flowing equation (1)

$$
\begin{equation*}
\Delta G^{\ddagger}=\Delta H^{\ddagger}-\mathrm{T} \Delta S^{\ddagger} \tag{1}
\end{equation*}
$$

| Temperature | 298 K | 303 K | 308 K |

### 6.4.5.4 Diels-Alder reaction between anthracene and $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{~L}_{3}(\mathrm{MeCN})_{2}$

Figure 6.4.70 Diels-Alder reaction of $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{~L}_{3}(\mathrm{MeCN})_{2}$ and anthracene

To an acetonitrile solution of $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{La}_{3}(\mathrm{MeCN})_{2}(0.35 \mathrm{mM}, 600 \mu \mathrm{~L}, 0.21 \mu \mathrm{~mol})$ in a NMR tube wrapped with aluminium foil, anthracene ( 20.0 mM in $\mathrm{CD}_{3} \mathrm{CN}, 10.5 \mu \mathrm{~L}, 0.21$ $\mu \mathrm{mol})$ was added and the tube was shaken in the dark. The mixture was let stand in the dark for 7 days at ambient temperature. Formation of $\mathrm{C}_{60}$ ant $@ \mathrm{Pd}_{2} \mathrm{~L}_{3}(\mathrm{MeCN})_{2}$ was not observed.

Figure 6.4.71 ${ }^{1} \mathrm{H}$ NMR spectra ( $500 \mathrm{MHz}, 298 \mathrm{~K}, \mathrm{CD}_{3} \mathrm{CN}$ ) of $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{~L}_{3}(\mathrm{MeCN})_{2}$ $(0.70 \mathrm{mM})$ mixture of $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{~L}_{3}(\mathrm{MeCN}) 2(0.35 \mathrm{mM})$ and 1 equivalent of anthracene after 7 days (bottom)

### 6.4.5.5 Diels-Alder reaction between DMA and $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{~L}^{\mathrm{Q}_{3}(\mathrm{MeCN})}{ }_{2}$

Figure 6.4.72 Diels-Alder reaction of $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{~L}_{3}(\mathrm{MeCN})_{2}$ and DMA

To an acetonitrile solution of $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{~L}_{3}(\mathrm{MeCN})_{2}(0.70 \mathrm{mM}, 600 \mu \mathrm{~L}, 0.42 \mu \mathrm{~mol})$ in a NMR tube wrapped with aluminium foil, 9,10-dimethylanthracene $(20.0 \mathrm{mM}$ in $\mathrm{CD}_{3} \mathrm{CN}, 21.0 \mu \mathrm{~L}, 0.42 \mu \mathrm{~mol}$ ) was added and the tube was shaken in the dark. The mixture was let stand in the dark for 1 h at ambient temperature. Besides the signals of $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{~L}_{3}(\mathrm{MeCN})_{2}$, a new set of signals appeared which showed temperature dependency.

### 6.4.5.6 VT-1 ${ }^{1} \mathrm{H}$ NMR measurements

Figure 6.4.73 ${ }^{1} \mathrm{H}$ NMR spectra ( $500 \mathrm{MHz}, 298 \mathrm{~K}, \mathrm{CD}_{3} \mathrm{CN}$ ) of mixture of $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{~L}_{3}(\mathrm{MeCN})_{2}$ and 1 equivalent of DMA

The sample was let stand for 10 min in the NMR spectrometer at each temperature to be sure that the temperature is stable during the measurement. Upon elevating the temperature, the ratio of $\mathrm{C}_{60} \mathrm{DMA} @ \mathrm{Pd}_{2} \mathrm{~L}_{3}(\mathrm{MeCN})_{2}$ to $\mathrm{Pd}_{2} \mathrm{~L}_{3}(\mathrm{MeCN})_{2}$ decreased. To confirm that the process is reversible, the ${ }^{1} \mathrm{H}$ NMR spectrum was measured at 298 K again after the measurements at the higher temperature.

### 6.4.6.1.3 Guest-exchange experiments

The sample was prepared as described in 6.4.2.5. To two solutions in NMR tubes of $\mathrm{C}_{60} \mathrm{DMA} \cdot \mathrm{C}_{60} @ \mathrm{Pd}_{4} \mathrm{~L}_{6}(\mathrm{Nap})_{2}(0.33 \mathrm{mM}, 631 \mu \mathrm{~L}, 0.21 \mu \mathrm{~mol})$, 10 equiv. of corannulene was added each. One of the NMR tube was darkened with alum foil and the other sample was exposed to daylight at room temperature for 3 days. In the darkened sample showed a neglectable guest exchange while the sample exposed to light showed guest-exchange from DMA to corannulene together with the observation of most probably the hetero Diels-Alder product of DMA and singlet oxygen.

Figure 6.4.79 ${ }^{1} \mathrm{H}$ NMR spectra of $\mathrm{C}_{60} \mathrm{DMA} \cdot \mathrm{C}_{60} @ \mathrm{Pd}_{4} \mathrm{~L}^{\mathrm{Q}}{ }_{6}(\mathrm{Nap}) 2(0.33 \mathrm{mM}, 642 \mu \mathrm{~L}, 0.21$ $\mu \mathrm{mol}, \mathrm{CD}_{3} \mathrm{CN}, 500 \mathrm{MHz}, 298 \mathrm{~K}$ ) after the guest-exchange experiments

## 7 Conclusion

Based on the molecular design previously established in our group, organic ligands having a curved $\pi$-surface have been synthesized. Self-assembly with Pd(II) yields coordination cages having a suitable cavity for $\mathrm{C}_{60}$ encapsulation. By using those coordination cages, the author had been investigating physical and chemical properties of $\mathrm{C}_{60}$ inside the cavities under the concepts of "Nano-confinement" and "Hierarchical assembly". $\mathrm{Pd}_{2} \mathrm{LP}_{4}$ can encapsulate $\mathrm{C}_{60}$ in a quantitative fashion and oneelectron reduction of the confined $\mathrm{C}_{60}$ leads to generation of $\mathrm{C}_{60}{ }^{\circ-}$ inside the cage. The generated $\mathrm{C}_{60}{ }^{\circ-}$ was found to be stabilized within the cage due to nano-confinement effects. The encapsulation capability of $\mathrm{Pd}_{2} \mathrm{LP}_{4}$ was further investigated towards carbon-rich aromatic molecules including $\mathrm{C}_{60}$ derivatives. Thanks to the curved $\pi-$ surface of the ligand, two molecules of corannulene can be encapsulated inside the cavity with a temperature dependency. In addition, a variety of $\mathrm{C}_{60}$ derivatives can be also accommodated inside the coordination cage. The coordination cage was further proven to work as a supramolecular mask for synthesis of $\eta^{2}-\mathrm{C}_{60} \mathrm{Pd}(0)_{\mathrm{n}}(\mathrm{n}=1,2)$ complexes. Such complexes were found to be formed inside the coordination cage by simple addition of $\operatorname{Pd}(0)(\mathrm{dba})_{2}$ to $\mathrm{C}_{60} @ \mathrm{Pd}_{2} \mathrm{LP}_{4}$. Furthermore, a pill-shaped coordination cage, $\mathrm{Pd}_{4} \mathbf{L}_{6}{ }_{6}(\mathrm{Nap})_{2}$, has been synthesized. $\mathrm{Pd}_{4} \mathbf{L}^{\mathrm{Q}_{6}}(\mathrm{Nap})_{2}$ has two pockets which allow encapsulation of two molecules of $\mathrm{C}_{60}$. Thanks to the molecular design, there is a nanoscopic space in between the encapsulated $\mathrm{C}_{60}$ s, which can be further used for investigation of guest-incorporation in between the outer surfaces of two C6os. Such host-guest studies have been investigated mostly in solid-state due to the difficulty of aligning $\mathrm{C}_{60}$ in an array. In the herein created nanoscopic space, single corannulene was found to be encapsulated via $\pi-\pi$ interactions with the $\mathrm{C}_{60} \mathrm{~S}$ surrounding leading to formation of a charge-transfer complex. On the other hand, when anthracene or its derivative was entrapped in the nano-space, a Diels-Alder reaction took place yielding a host-guest complex holding $\mathrm{C}_{60}$ and its Diels-Alder adduct with anthracene (derivative) quantitatively. It was found that the Diels-Alder reaction has a faster reaction rate probably via stabilization of a transition state through $\pi-\pi$ interactions with the neighboring C60. Further, an evidence of the continuous Diels-Alder and its retro reaction inside the pill-shaped cage was found by 2D EXSY NMR measurements. To conclude, these results imply a potential of coordination cages as a host for the investigation of physical properties of $\mathrm{C}_{60}(\mathrm{~s})$ under nano-confinement as well as in hierarchical assembly.

| Abbreviations |  |
| :---: | :---: |
| Å | Ångström |
| ${ }^{\circ} \mathrm{C}$ | Celcius |
| $\mathrm{BF}_{4}$ | Tetrafluoroborate |
| $\mathrm{CH}_{3} \mathrm{CN}$ | Acetonitrile |
| $\mathrm{CHCl}_{3}$ | Chloroform |
| COSY | Correlated spectroscopy |
| $\mathrm{CS}_{2}$ | Carbon disulfide |
| CV | Cyclic voltammetry |
| dba | Dibenzylidenaceton |
| DFT | Density Functional theory |
| DOSY | Diffusion ordered spectroscopy |
| EPR equiv. | Electron paramagnetic resonance equivalent |
| ESI-MS | Electrospray ionization mass spectroscopy |
| $\mathrm{Et}_{2} \mathrm{O}$ | Diethyl ether |
| EXSY | Exchange spectroscopy |
| GPC | Gel permeation chromatography |
| h | Hour |
| HOMO | Highest occupied molecular orbital |
| K | Kelvin |
| LED | Light-emitting diode |
| LUMO | Lowest unoccupied molecular orbital |
| MeCN | Acetonitrile |
| MeOH | Methanol |
| MHz | Megahertz |
| m/z | Mass-to-charge ratio |
| mM | $\mathrm{mmol} \cdot \mathrm{L}^{-1}$ |
| NIR | Near infrared region |
| nm | nanometer |
| NMR | Nuclear magnetic resonance |
| NOESY | Nuclear overhauser effect spectroscopy |
| PC61 ${ }^{\text {BM }}$ | Phenyl-C61-butyric acid methyl ester |
| ppm | Parts per million |
| r.t. | Room temperature |
| SOMO | Singly occupied molecular orbital |
| TBAPF6 | Tetrabutylammonium hexafluorophosphate |
| UV-Vis | Ultraviolet-visible |
| VT | Variable temperature |

## Acknowledgements:

To accomplish this Ph.D. dissertation, I have been provided countless help and support from a variety of perspectives. Here, I would like to show my acknowledgements to those people who kindly helped me.
The biggest gratitude goes to my supervisor, Prof. Dr. Guido H. Clever. He kindly accepted me as a Ph.D. student and let me follow my curiosity as a form of research. We first met in Sendai, Japan, where he delivered a plenary lecture about the beautiful "Clever chemistry". My English was very poor at that moment, however, he listened to me attentively and gave me a lot of suggestions and advices varied from scholarship application to life in Germany. Similarly, he has given me many opportunities to talk about my research, helped me greatly with my career, shared his experience with me and so forth since I have joined this group. Although, most of my stay in Germany was under the Corona pandemic, I could fully perform my research thanks to his fine and continuous supports.
Second, I appreciate Prof. Dr. Max M. Hansmann for taking a part of the examination committee. Since I have talked with him at Tag der Chemie about my research, I had been willing to ask him to be my second examiner.
If one of the people that I have met during this study would have been lacking, I could not have accomplished this dissertation. I would like to thank Birgit Thormann and Dr. Gabriele Trötscher-Kaus for all the support and help they gave me. Thanks to them, I could spend the time in this group quite comfortably.
I would like to thank Dr. Ananya Baksi and Laura Schneider for the ESI MS measurements. I thank Prof. Dr. Wolf G. Hiller and André Platzek for help with the NMR measurements. I thank Dr. Julian J. Holstein for crystallographic analysis. I learned a lot from him. I appreciate Shari L. Meichsner and Prof. Dr. Müge Kasanmascheff for the EPR measurements and discussion. I also appreciate DESY for the access to synchrotron beam time. I thank Prof. Dr. Steffen for the access to the UV-Vis NIR absorption spectrometer. I appreciate DAAD for financial support. I am grateful to Christoph Drechsler for discussion about theoretical studies. I thank Armin Durmisevic, Christoph Drechsler, Elie Benchimol, Laura Neukirich, and Dr. Gabriele Trötscher-Kaus for polishing this thesis. I would like to thank Laura Neukirch and Dr. Gabriele Trötscher-Kaus for the contribution of the abstract in German.
I would like to thank Dr. Jacopo Tessarolo and Dr. Pedro Montes-Tolentino for staying together with me most of the time in Germany. They are colleagues, friends, brothers, and very valuable to me. If they would not have been with me, I would have left much
earlier. I would like to thank Elie Benchimol for caring me whenever I was down. The environment of the group became much brighter since he has joined this group. I really appreciate my roomies Dr. Irene Regeni and Dr. Lukas Stratmann for accommodating me for several months while I was homeless. I really enjoyed the time staying with them. I am thankful to André Platzek and Kristina Ebbert for providing food with me. I could maintain my weight thanks to them. When I would be asked what my favorite German food is someday, Kristina's Eintopf would be my answer. I would like to thank Dr. Qianqian Yan for taking a good care of me since we have started sharing our office. She always (unintentionally) made me laugh. We have also cheered each other while we had been writing dissertation.
I would like to thank my students Alicia Dullweber and Thomas Kembügler for working with me.
I appreciate everybody in the Clever group for their friendship and support.
Last but not least, I would like to thank my family for their selfless devotion since I was born. I am happier than others just because I am a child of my parents
