Abstract

In the problem of testing the equality of $k$ regression curves from independent samples we discuss three methods using nonparametric estimation techniques of the regression function. The first test is based on a linear combination of estimators for the integrated variance function in the individual samples and in the combined sample. The second approach transfers the classical one-way analysis of variance to the situation of comparing nonparametric curves, while the third test compares the differences between the estimates of the individual regression functions by means of an $L^2$-distance. We prove asymptotic normality of all considered statistics under the null hypothesis, local and fixed alternatives with different rates corresponding to the various cases. Additionally consistency of a wild bootstrap version of the tests is established. In contrast to most of the procedures proposed in the literature the methods introduced in this paper are also applicable in the case of different design points in each sample and heteroscedastic errors. A simulation study is conducted to investigate the finite sample properties of the new tests and a comparison with recently proposed and related procedures is performed.

AMS Classification: Primary 62G05
Keywords and Phrases: Nonparametric analysis of covariance, variance estimation, comparison of regression curves, goodness-of-fit, wild bootstrap.

1 Introduction

An important problem in applied regression analysis is the comparison of a response $Y$ across several groups in the presence of a covariate effect. In general this model can be written as

$(1.1) \quad Y_{ij} = g_i(t_{ij}) + \sigma_i(t_{ij})\varepsilon_{ij}$

$(i = 1, \ldots, k, j = 1, \ldots, n)$, where $\varepsilon_{ij}$ are independently identically distributed errors, $g_i, \sigma_i$ are the regression and variance function in the $i$th group $(i = 1, \ldots, k)$ and the covariate $t_{ij}$ varies in the
interval $[0,1]$. In this paper we are interested in the problem of testing the equality of the mean functions, i.e.

\[(1.2) \quad H_0 : g_1 = g_2 = \ldots = g_k \quad \text{versus} \quad H_1 : g_i \neq g_j \quad (\exists \ i, j \in \{1, \ldots, k\})\].

Much effort has been devoted to this problem in the recent literature [see e.g. Härdle and Marron (1990), King, Hart and Wehrly (1991), Hall and Hart (1990), Delgado (1993), Young and Bowman (1995), Kulasekera (1995), Kulasekera and Wang (1997), Hall, Huber and Speckman (1997) or Dette and Munk (1998)]. Most authors concentrate on the case of two samples ($k = 2$) and a homoscedastic error in all groups. Härdle and Marron (1990) consider a semi-parametric approach in the case of equal designs (i.e. $n_1 = \ldots = n_k$, $t_{ij} = t_j$, $i = 1, \ldots, k$). King, Hart and Wehrly (1990) and Hall and Hart (1990) discuss the completely nonparametric homoscedastic (i.e. $\sigma_i^2(t) = \sigma^2$, $i = 1, \ldots, k$) model in the case of equal designs points. While the latter approach can be generalized to the case of unequal design points [see Hall and Hart (1990)], Kulasekera (1995) points out some drawbacks of the test in this case and proposes several alternatives which are applicable in the model (1.1) under the additional assumption of homoscedasticity in all groups. This approach can detect alternatives which converge to the null at a rate of order $1/\sqrt{n}$ but the author also mentions some practical problems of this procedure. On the one hand the level of the test depends sensitively on the smoothing parameter, on the other hand larger noises yield levels substantially different from the nominal levels [see also Kulasekera and Wang (1997) for a detailed simulation study and data-driven guidelines for bandwidth selection]. Moreover, a generalization to a heteroscedastic error or a multivariate predictor seems to be difficult. A rather different test was introduced by Young and Bowman (1995) who generalized the one-way analysis of variance to the model (1.1). Under the assumption of normally distributed homoscedastic errors over all groups these authors proposed a $\chi^2$-approximation for the distribution of the test statistic. Although the finite sample properties of the test under these assumptions look promising, a generalization to the general heteroscedastic, nonnormal case does not appear trivial and the asymptotic properties of this test have not been investigated so far. To our knowledge the problem of testing the equality of the regression functions in the completely heteroscedastic model (1.1) with a univariate predictor and unequal design points was firstly considered by Dette and Munk (1998) who introduced a simple estimator of the distance

$$\sum_{i<j} \int_0^1 [g_i(t) - g_j(t)]^2 dt$$

and proved an asymptotic normal law with a $\sqrt{n}$-rate for a corresponding test statistic. As a consequence this test is not efficient from an asymptotic point of view.

In this paper we discuss various tests for the hypothesis (1.2) which are directly applicable in the general model (1.1), do not require any additional assumptions (as homoscedasticity or equal design points) and improve on the asymptotic efficiency of the test of Dette and Munk (1998). Moreover, the new methods can easily be extended to the case of multivariate predictors. A first method for testing the hypothesis (1.2) is based on a difference between a nonparametric variance estimator in the combined sample $\{Y_{ij} \mid j = 1, \ldots, n_i; i = 1, \ldots, k\}$ and the corresponding estimators in the individual samples $\{Y_{ij} \mid j = 1, \ldots, n_i\}$ and yields in fact an estimator of an alternative measure of equality. Our second proposal is to use Young and Bowman’s (1995) test also in the situation of a heteroscedastic error. Finally, we suggest a generalization of King, Hart and Wehrly’s (1997) test to the general setup (1.1), which compares the estimates of the regression functions in the individual samples. This method is closely related to an approach introduced by Rosenblatt (1975) in the context of testing
independence and further developed by Härdle and Mammen (1993) and González Manteiga and Cao (1993) for the problem of testing the parametric form of a regression function. We prove asymptotic normality of all proposed test statistics under the null hypothesis and fixed alternatives with different rates of convergence corresponding to both cases. In Section 2 we introduce the different methods, state the main asymptotic results and discuss various links between the different approaches. In Section 3 we investigate the finite sample properties of some of the proposed tests and perform a comparison with alternative procedures which have recently been suggested in the literature [see Hall and Hart (1990), Delgado (1993), Kulasekera (1995), Kusalekera and Wang (1997)]. It is demonstrated that a wild bootstrap version of the test based on the difference of variance estimators has excellent finite sample properties and is very often remarkably more powerful than several other tests proposed in the literature, which can detect alternatives converging to the null at a parametric rate. Finally, some of the proofs, which are cumbersome, are given in the appendix of Section 4.

2 Testing the equality of regression functions by kernel based methods

In order to motivate the different methods for testing the hypothesis of the form (1.2) and to investigate the asymptotic distribution of the corresponding test statistics we need a few regularity assumptions. Let \( N = \sum_{i=1}^{k} n_i \) denote the total sample size and assume

\[
\frac{n_i}{N} = \kappa_i + O\left(\frac{1}{N}\right), \quad i = 1, \ldots, k
\]

for given constants \( \kappa_1, \ldots, \kappa_k \in (0, 1) \). Let \( r_1, \ldots, r_k \) denote positive densities on the interval \([0, 1]\) such that the design points \( t_{ij} \) satisfy

\[
\int_{0}^{t_{ij}} r_i(t) \, dt = \frac{j}{n_i}; \quad j = 1, \ldots, n_i, i = 1, \ldots, k
\]

[see Sacks and Ylvisaker (1970)]. Throughout this paper we will assume the continuity of the variance functions \( \sigma_i^2(\cdot) \) ( \( i = 1, \ldots, k \) and additionally that the design densities in (2.2) and the regression functions are sufficiently smooth, i.e.

\[
g_j, r_j \in C^r[0, 1], \quad j = 1, \ldots, k
\]

where \( r \geq 2 \) and \( C^r[0, 1] \) denotes the space of \( r \)-times continuously differentiable functions on the interval \([0, 1]\). Let

\[
\hat{g}_i(t) = \frac{\sum_{j=1}^{n_i} K\left(\frac{t-t_{ij}}{h_i}\right) Y_{ij}}{\sum_{j=1}^{n_i} K\left(\frac{t-t_{ij}}{h_i}\right)}
\]

denote the Nadaraya-Watson estimator of the \( i \)th regression function \( g_i \) and \( h_i \) the corresponding bandwidth [see Nadaraya (1964) and Watson (1964)]. We assume that the kernel in (2.4) is supported on a compact interval, say \([-1, 1]\), and of order \( r \geq 2 \) [see Gasser, Müller and Mammitzsch (1985)], i.e.

\[
\frac{(-1)^j}{j!} \int_{-1}^{1} K(u) u^j \, du = \begin{cases} 
1 & : \quad j = 0 \\
0 & : \quad 1 \leq j \leq r - 1 \\
k_r \neq 0 & : \quad j = r,
\end{cases}
\]

3
where \( \int_{-1}^{1} K^2(u)du < \infty \).

If the hypothesis of equal regression functions is valid, the total sample could be used to estimate the common regression, i.e.

\[
g(t) = \frac{\sum_{i=1}^{k} \sum_{j=1}^{n_i} K\left(\frac{t-t_{ij}}{h}\right) Y_{ij}}{\sum_{i=1}^{k} \sum_{j=1}^{n_i} K\left(\frac{t-t_{ij}}{h}\right)},
\]

where \( h \) is a further bandwidth. For the sake of simplicity the asymptotic analysis of the statistics proposed below is performed for the case of equal bandwidths \( h_i = h \) \((i = 1, \ldots, k)\) in the estimators (2.4) and (2.6) where the bandwidth \( h \) satisfies

\[
Nh^2 \to \infty; \quad h = O(N^{-2/(d+1)}).
\]

### 2.1 Comparing variance estimators

Our first measure of equality between the different regression functions is obtained by comparing the nonparametric variance estimators of the individual samples with a nonparametric variance estimator of the pooled sample. To be precise let

\[
\sigma_i^2 = \frac{1}{n_i} \sum_{j=1}^{n_i} (Y_{ij} - \hat{g}_i(t_{ij}))^2 \quad (i = 1, \ldots, k)
\]

denote the estimator of the variance of the \( i \)th sample introduced by Hall and Marron (1990), where \( \hat{g}_i \) is the nonparametric estimator of the regression function in the \( i \)th sample defined in (2.4). Although these authors considered only a homoscedastic model it will be shown in the appendix (see Lemma 4.0) that in the heteroscedastic model \( \sigma_i^2 \) consistently estimates the integrated variance function \( \int_0^1 \sigma_i^2(t) r_i(t) dt \) of each sample \((i = 1, \ldots, k)\). In the following we will consider the analogue of (2.8) for the total sample size

\[
\hat{\sigma}^2 = \frac{1}{N} \sum_{i=1}^{k} \sum_{j=1}^{n_i} (Y_{ij} - \hat{g}(t_{ij}))^2.
\]

It is proved in the appendix that under the hypothesis of equal regression curves this is essentially an estimator for a convex combination of the individual integrated variance functions, i.e.

\[
\sum_{i=1}^{k} \kappa_i \int_0^1 \sigma_i^2(t) r_i(t) dt.
\]

For these reasons we propose as a test statistic

\[
T_N^{(1)} = \hat{\sigma}^2 - \frac{1}{N} \sum_{i=1}^{k} n_i \sigma_i^2.
\]

The asymptotic properties of the statistic \( T_N^{(1)} \) are listed in the following theorem.
Theorem 2.1. Assume that (2.1), (2.2), (2.3), (2.5), (2.7) are satisfied.

(i) If the hypothesis of equal regression functions is valid, then the statistic $T_{N}^{(1)}$ satisfies

$$N \sqrt{h}(T_{N}^{(1)} - B_{k}^{(1)} h^{2r} - \frac{1}{Nh} D_{k}^{(1)}) \overset{D}{\rightarrow} N(0, \beta_{k,1}^{2})$$

where

$$(2.10) \quad B_{k}^{(1)} = k_{r}^{2} \int_{0}^{1} ((g_{i}, \hat{R}^{(r)}) - g_{i} R^{(r)})^{2}(t) \frac{dt}{R(t)} - k_{r}^{2} \sum_{i=1}^{k} \sum_{j=1}^{k} \kappa_{j} \int_{0}^{1} ((g_{i}, r_{j})^{(r)} - g_{i} r_{j}(t))^{2} \frac{dt}{r_{j}(t)}$$

$$D_{k}^{(1)} = \left[ \int_{-1}^{1} K^{2}(u) \, du - 2K(0) \right] \sum_{j=1}^{k} \left( \int_{0}^{1} \frac{\kappa_{j} \sigma_{j}^{2}(t) r_{j}(t)}{R(t)} \, dt - \int_{0}^{1} \sigma_{j}^{2}(t) \, dt \right),$$

the asymptotic variance is given by

$$(2.11) \quad \beta_{k,1}^{2} = 2 \int_{-1}^{1} (2K - K \ast K)^{2}(u) \, du \left\{ \sum_{j=1}^{k} \int_{0}^{1} \sigma_{j}^{2}(t) \left( \frac{\kappa_{j} r_{j}(t)}{R(t)} - 1 \right)^{2} \, dt \right. \right.$$  

$$+ \left. \sum_{j=1}^{k} \sum_{i \neq j} \int_{0}^{1} \sigma_{j}^{2}(t) \sigma_{i}^{2}(t) \frac{\kappa_{j} r_{j}(t) \kappa_{i} r_{i}(t)}{R^{2}(t)} \, dt \right\},$$

$K \ast K$ is the convolution of the kernel with itself and $\hat{R}$ denotes the convex combination of the underlying densities, i.e.

$$\hat{R}(t) = \sum_{j=1}^{k} \kappa_{j} r_{j}(t).$$

(ii) Under the alternative $g_{i} \neq g_{j}$ ($\exists i, j \in \{1, \ldots, k\}$) the statistic $T_{N}^{(1)}$ satisfies

$$\sqrt{N}(T_{N}^{(1)} - M_{k,1}^{2}) \overset{D}{\rightarrow} N(0, \gamma_{k,1}^{2})$$

where

$$(2.12) \quad M_{k,1}^{2} = \sum_{j=1}^{k} \sum_{i=1}^{k} \int_{0}^{1} (g_{j} - g_{i})^{2}(t) \frac{\kappa_{j} r_{j}(t) \kappa_{i} r_{i}(t)}{R(t)} \, dt$$

and the asymptotic variance is given by

$$(2.13) \quad \gamma_{k,1}^{2} = 4 \sum_{j=1}^{k} \int_{0}^{1} \left( \sum_{i \neq j}^{k} (g_{j}(t) - g_{i}(t)) \frac{\kappa_{j} r_{j}(t)}{R(t)} \right)^{2} \sigma_{j}^{2}(t) \kappa_{j} r_{j}(t) \, dt.$$

2.2 An ANOVA-type statistic

The following method for testing the equality of the regression functions was introduced by Young and Bowman (1995) in the context of a homocedastic normal distribution for the error over all $k$ samples. The corresponding statistic is closely related to the difference of variance estimators introduced in
Section 2.1. It will be shown in this section that the method proposed by these authors is also applicable in the general situation of nonnormal heteroscedastic errors. The test statistic of Young and Bowman (1995) is motivated by the classical one-way analysis of variance and given by

\[ Y_N = \frac{N}{s^2} T_N^{(2)}, \]

where

\[ T_N^{(2)} = \frac{1}{N} \sum_{i=1}^{k} \sum_{j=1}^{n_i} [\hat{g}(t_{ij}) - \hat{g}_i(t_{ij})]^2, \]

\( \hat{g}, \hat{g}_1, \ldots, \hat{g}_k \) are defined in (2.6) and (2.4), respectively, and

\[ s^2 = \frac{1}{2(N-k)} \sum_{i=1}^{k} \sum_{j=1}^{n_i-1} (Y_{i,j+1} - Y_{i,j})^2 \]

is a pooled mean of the difference based estimators for the variances in the individual samples [see e.g. Rice (1984)]. The statistic \( s^2 \) is also a consistent estimator of

\[ s^2 = \frac{1}{k} \int_{0}^{1} \sigma_j^2(t) r_j(t) dt \]

which follows by a straightforward calculation [see also Kulasekera and Wang (1997) for a related result under homoscedasticity]. Note that there is a strong link between the statistics \( T_N^{(1)} \) and \( T_N^{(2)} \). While the statistic \( T_N^{(1)} \) is comparing the regression functions through residual sums of squares the statistic \( T_N^{(2)} \) compares the curves through the fitted values. In the case of a fixed design, equal homoscedastic variances in all groups and a normally distributed error Young and Bowman (1995) proposed a \( \chi^2 \)-approximation of the corresponding test statistic under the null hypothesis. These restrictions allow a rapid and accurate calculation of the \( p \)-value [see Young and Bowman (1995) for more details]. It is also worthwhile to mention that the use of the same smoothing parameters in the estimates of the individual regression function yields a direct cancelation of the bias.

Obviously, the numerator of \( Y_N \) given in (2.14) is an estimate for an appropriate measure of equality of the \( k \) regression curves and we will also use \( T_N^{(2)} \) as a test statistic for the hypothesis (1.2) in the general situation of not necessarily homoscedastic and normally distributed errors. The following result makes this heuristic argument more precise and provides the asymptotic properties of the statistic (2.14). As a by product it also proves consistency of the test proposed by Young and Bowman (1995) if the required assumptions for the finite sample size approximation used by these authors are not satisfied. Moreover critical values could be obtained from an approximation by a normal distribution or a wild bootstrap procedure as proposed in Section 3.

**Theorem 2.2.** Assume that (2.1), (2.2), (2.3), (2.5), (2.7) are satisfied.

(i) If the hypothesis of equal regression curves is valid, then the statistic \( T_N^{(2)} \) defined in (2.14) satisfies

\[ N \sqrt{h}(T_N^{(2)} + E_k^{(2)} h^2 - \frac{D_k^{(2)}}{Nh}) \overset{D}{\to} \mathcal{N}(0, \beta_{k,2}^2) \]
where $B_k^{(2)} = B_k^{(1)}$ is defined in (2.10),

$$D_k^{(2)} = \int_1^1 K^2(u) du \sum_{j=1}^k \int_0^1 \left(1 - \kappa_j r_j(t) \frac{R_j(t)}{R(t)}\right) \sigma_j^2(t) dt,$$

and the asymptotic variance is given by

$$\beta_{k,2}^2 = 2 \int_1^1 (K \ast K)^2(u) du \left\{ \sum_{j=1}^k \int_0^1 \sigma_j^4(t) \left(\frac{k \kappa_j r_j(t)}{R(t)} - 1\right)^2 dt \right. + \left. \sum_{j=1}^k \sum_{l=1}^k \int_0^1 \sigma_j^2(t) \sigma_l^2(t) \frac{k \kappa_j r_j(t) \kappa_l r_l(t)}{R^2(t)} dt \right\}$$

(ii) Under the alternative $g_i \neq g_j$ ($\exists i, j \in \{1, \ldots, k\}$) the statistic $T_N^{(2)}$ defined in (2.14) satisfies

$$\sqrt{N}(T_N^{(2)} - M_{k,2}^2) \xrightarrow{D} N(0, \gamma_{k,2}^2)$$

where $M_{k,2}^2 = M_{k,1}^2$ and $\gamma_{k,2}^2 = \gamma_{k,1}^2$ are defined in (2.12) and (2.13), respectively.

### 2.3 Pairwise comparison of regression curves

Following Rosenblatt (1975), Härdle, Mammen (1993) and González Manteiga, Cao (1993) an obvious alternative test of the hypothesis (1.2) could be obtained from a pairwise comparison of the estimators of the regression functions. To this end we consider the statistic

$$T_N^{(3)} = \sum_{i=1}^k \sum_{j=1}^{i-1} \int_0^1 [\hat{g}_i(t) - \hat{g}_j(t)]^2 w_{ij}(t) dt$$

where $w_{ij}(\cdot)$ are positive weight functions satisfying $w_{ij} = w_{ji}$ ($1 \leq j < i \leq k$). A similar statistic was considered by King, Hart and Wehrly (1991) in the case of two samples with equal design points (here the integral was approximated by a sum and a constant weight was used). A calculation similar as given in the proof of Lemma 4.0 of the appendix shows that

$$E[T_N^{(3)}] = \begin{cases} \frac{1}{Nh} D_k^{(3)} + O(\frac{1}{N}) & \text{under } H_0 \\ \frac{1}{Nh} D_k^{(3)} + M_{k,3}^2 + O(\frac{1}{N}) & \text{under } H_1 \end{cases}$$

where the constants $D_k^{(3)}, M_{k,3}^2$ are defined by

$$D_k^{(3)} = \int K^2(u) du \sum_{j=1}^k \int_0^1 \frac{\sigma_j^2(t)}{k \kappa_j r_j(t)} \left(\sum_{l=1}^k w_{jl}(t)\right) dt,$$

$$M_{k,3}^2 = \sum_{j=1}^k \sum_{l=1}^k \int_0^1 (g_j - g_l)^2(t) w_{jl}(t) dt.$$
Theorem 2.3. Assume that (2.1), (2.2), (2.3), (2.5), (2.7) are satisfied.

(i) If the hypothesis of equal regression curves is valid, then the statistic $T^{(3)}_N$ defined in (2.18) satisfies

$$N\sqrt{h}(T^{(3)}_N - \frac{1}{Nh} D^{(3)}_k) \xrightarrow{D} N(0, \beta^2_{k,3})$$

where the asymptotic variance is defined by

$$(2.22) \quad \beta^2_{k,3} = \int_0^1 (K*K)^2(u) \left\{ \sum_{j=1}^k \int_0^1 \frac{\sigma^2_j(t) \sum_{i=1}^k w_{ji}(t)}{K_{ji}(t)} dt \right\} du,$$

(ii) Under the alternative $g_i \neq g_j (\exists i, j \in \{1, \ldots, k\})$ the statistic $T^{(3)}_N$ defined in (2.18) satisfies

$$\sqrt{N}(T^{(3)}_N - M^2_{k,3}) \xrightarrow{D} N(0, \gamma^2_{k,3})$$

where $M^2_{k,3}$ is defined in (2.21) and the asymptotic variance is given by

$$\gamma^2_{k,3} = 4 \sum_{i=1}^k \sum_{j=1}^k \sum_{i \neq j} \int_0^1 (g_i(t) - g_i(t))(g_i(t) - g_j(t))w_{ji}(t)w_{ij}(t) \frac{\sigma^2_j(t)}{K_{ji}(t)} dt.$$

Remark 2.4. It is worthwhile to mention that there is a strong link between the three statistics $T^{(1)}_N$, $T^{(2)}_N$, $T^{(3)}_N$, which can nicely be explained by looking at the classical one-way analysis of variance model, where

$$X_{ij} \sim N(\mu_i, \sigma^2), \quad j = 1, \ldots, n; \quad i = 1, \ldots, k.$$ 

Here the denominator of the corresponding F-test corresponds to the statistic $T^{(2)}_N$ of Young and Bowman (1995) and can be decomposed as

$$(2.23) \quad \sum_{i=1}^k n_i \left( \bar{X}_i - \bar{X} \right)^2 = \sum_{i=1}^k \sum_{j=1}^{n_i} \left( X_{ij} - \bar{X}_i \right)^2 - \sum_{i=1}^k \sum_{j=1}^{n_i} \left( X_{ij} - \bar{X}_i \right)^2,$$

where the first term on the right hand side is an estimator of the variance from the pooled sample (assuming equal means in all $k$ samples) and the second term is a combination of the variance estimators in the individual samples. Consequently the right hand side of (2.23) corresponds to the statistic $T^{(1)}_N$ introduced in Section 2.1. Therefore in linear models both statistics are equivalent, while for nonparametric models there appear differences because the cross product terms involve a nonvanishing bias. Similary, we have the representation

$$\sum_{i=1}^k n_i \left( \bar{X}_i - \bar{X} \right)^2 = \frac{1}{2N} \sum_{i=1}^k \sum_{j=1}^k n_i n_j \left( \bar{X}_i - \bar{X}_j \right)^2$$

which establishes an analogy between the statistics $T^{(2)}_N$ and $T^{(3)}_N$. 

8
2.4 Some asymptotic power comparisons

As a consequence of Theorem 2.1 - 2.3 we obtain consistent, asymptotic level \( \alpha \) tests by rejecting the hypothesis of equal regression curves whenever

\[
N \sqrt{h} (T_N^{(i)} - B_k^{(i)} h^{2r} - D_k^{(i)} h) > \beta_{k,i} u_{1-\alpha}, \quad i = 1, 2, 3
\]

where \( B_k^{(3)} = 0 \), \( B_k^{(i)}, D_k^{(i)}, \beta_{k,i} \) are defined in Theorem 2.1 - 2.3 and have to be replaced by consistent estimators. In the following section we will illustrate the performance of a wild bootstrap version of the tests given by (2.24), because the speed of convergence under the null hypothesis is usually rather slow [see also Azzalini and Bowman (1993), Häjek and Tjostheim (1995) or Alcalá, Christóbal and González Manteiga (1999) for similar observations].

Moreover, the second part of Theorem 2.1 - 2.3 provides an important advantage in the application of these tests (compared to most of the procedures proposed in the literature). It is well known that in the problem of testing goodness-of-fit the essential error is the type II error and a large observed \( p \)-value does not give any empirical evidence for the null hypothesis [see e.g. Berger and Delampady (1987), Staudte and Sheather (1990)]. The second part of Theorem 2.1 - 2.3 now provides an approximation for the type II error of the test by

\[
P(\neg \text{"rejection"}) \sim \Phi \left( \frac{\sqrt{N}}{\gamma_{k,i}} \left\{ M_{k,i} - \frac{u_{1-\alpha} \beta_{k,i}}{N \sqrt{h}} \right\} \right) \sim \Phi \left( \frac{\sqrt{N} M_{2,i}}{\gamma_{k,i}} \right), \quad i = 1, 2, 3.
\]

We remark that the approximation by a normal distribution under fixed alternatives is more reliable than under the null hypothesis, because it is similar to the approximation by a normal distribution in the classical central limit theorem (see the proof in Section 4.3). Moreover, the second part of Theorem 2.1 - 2.3 can also be used for testing the precise hypotheses [see Berger and Delampady (1987)]

\[
H_0 : M_{k,i}^2 > \Delta \quad \text{versus} \quad H_1 : M_{k,i}^2 \leq \Delta
\]

where \( \Delta \) is a sufficiently small constant such that whenever \( M_{k,i}^2 \leq \Delta \) the experimenter agrees to analyze the data under the assumption of equal regression curves. Note that the rejection of \( H_0 \) in (2.26) allows us to show that the regression functions are “close” at a controlled error rate.

**Remark 2.5.** The possibility of choosing the weight functions in (2.18) leaves some freedom for the statistic \( T_N^{(3)} \) and using

\[
w_{ij} = \frac{\kappa_i r_i \kappa_j r_j}{R}
\]

gives a statistic with an asymptotically similar behaviour as described in Theorem 2.1 and 2.2 for the tests based on \( T_N^{(1)} \) and \( T_N^{(2)} \). This weight function is very natural because under the additional assumption of homoscedasticity it maximizes the asymptotic power for comparing the curves \( g_i \) and \( g_j \) with respect to the choice of the weight function. To be precise assume that \( k = 2 \), then a straightforward calculation [see also the derivation of (2.25)] shows that the probability of rejection is an increasing function of

\[
\frac{(M_{2,3}^2)^2}{\gamma_{2,3}^2} = \frac{\left( \int_0^1 (g_1 - g_2)^2(t) u_{12}(t) dt \right)^2}{\sigma^2 \int_0^1 (g_1 - g_2)^2(t) u_{12}^2(t) \left( \frac{1}{\kappa_1 r_1(t)} + \frac{1}{\kappa_2 r_2(t)} \right) dt} \leq \frac{1}{\sigma^2} \int_0^1 (g_1 - g_2)^2 \left( \frac{1}{\kappa_1 r_1(t)} + \frac{1}{\kappa_2 r_2(t)} \right)^{-1} dt = \frac{(M_{2,1}^2)^2}{\gamma_{2,1}^2}
\]
where $M^2_{2,1} = M^2_{2,2}$ and $\gamma^2_{2,1} = \gamma^2_{2,2}$ are defined in (2.12) and (2.13), respectively, and the second line follows from Cauchy’s inequality. Now discussing the equality in (2.28) shows that the maximal power (with respect to the choice of the weight function $w_{12}$) is obtained by the weight (2.27). For these reasons the tests based on $T_N^{(2)}$ [Young and Bowman (1995)] and $T_N^{(1)}$ [proposed in Section 2] should be prefered because they automatically adapt to the best possible (but unknown) weight function for the maximization of the power at any fixed alternative.

**Remark 2.6.** In the remaining part of this section we will concentrate on the asymptotic behavior of the different tests with respect to local alternatives. For the sake of transparency we will concentrate on the case of $k = 2$ samples. There is no difference in the discussion of the general situation of $k \geq 3$ regression functions. We will adopt an approach of Rosenblatt (1975), who proposed to consider alternatives of the form

$$g_2(\cdot) = g_1(\cdot) + \delta_N s\left(\frac{\cdot - c}{\gamma_N}\right)$$

where $s$ is a continuously differentiable function of order $r$ and $c \in [0,1]$ a given constant. $\delta_N$ and $\gamma_N$ are sequences converging to 0 such that

$$\delta_N^2 \gamma_N = \frac{1}{N \sqrt{h}} , \quad \delta_N = o(1) , \quad \gamma_N^{-1} = o(h^{2r-1})$$

(a typical example in the case $r = 2$ is $h = N^{-2/3}$, $\delta_N = N^{-13/36}$ and $\gamma_N = N^{-1/6}$). For alternatives of the form (2.29) satisfying (2.30) it follows by similar arguments as given in the appendix for the proof of Theorem 2.1 that

$$N \sqrt{h} \left( T_N^{(i)} - B_k^{(i)} h^{2r} - \frac{D_k^{(i)}}{N h} \right) \xrightarrow{p} \mathcal{N}(\mu^{(i)}, \beta_k^{2,i})$$

where the constants $B_k^{(i)}$, $D_k^{(i)}$ and $\beta_k^{2,i}$ are defined in Theorem 2.1-2.3 (note that $B_k^{(3)} = 0$) and

$$\mu^{(i)} = \begin{cases} \left( \int_0^1 s^2(x)dx \cdot \frac{\kappa_1 \kappa_2 r_1(c)r_2(c)}{\kappa_1 r_1(c) + \kappa_2 r_2(c)} \right) & \text{if } i = 1, 2 \\ \int_0^1 s^2(x)dx \cdot w_{12}(c) & \text{if } i = 3 \end{cases}$$

A similar result is obtained for local alternatives of the form (2.29) with $c = 0$ and $\gamma_N = 1$, i.e. $g_1 = g_2 + s \cdot (N \sqrt{h})^{-1/2}$. In this case (2.31) is still valid, with a different expectation in the limit distribution, i.e.

$$\mu^{(i)} = \begin{cases} \left( \int_0^1 s^2(x) \frac{\kappa_1 \kappa_2 r_1(x)r_2(x)}{\kappa_1 r_1(x) + \kappa_2 r_2(x)} dx \right) & \text{if } i = 1, 2 \\ \int_0^1 s^2(x)w_{12}(x)dx & \text{if } i = 3 \end{cases}$$

For an asymptotic analysis of the three testing procedures with respect to these local alternatives we use the optimal (but unknown) weight function (2.27) for $w_{12}$ in the definition of the statistic
\( T_N^{(3)} \). The comparison can now easily be performed by looking at the different variances in (2.31) and observing the relation

\[
\int (K * K)^2(x) dx \leq \int K^2(x) dx \leq \int (2K - K * K)^2(x) dx
\]

which has been proved by Biedermann and Dette (2000). From this inequality it follows that \( \beta_{2,2}^{(3)} = \beta_{2,3}^{(2)} \leq \beta_{2,1}^{(2)} \) and consequently the procedures based on \( T_N^{(2)}, T_N^{(3)} \) are asymptotically more efficient as the test based on \( T_N^{(1)} \).

However, some care is necessary with this interpretation, because the speed of convergence in (2.31) is rather slow and the asymptotic analysis usually requires a rather large sample size [see Azzalini and Bowman (1993), Hjellvik and Tjostheim (1995) or Alcalá, Christóbal and González Manteiga (1999) for similar observations]. For realistic sample sizes the approximation (2.25) indicates a similar behaviour of all three methods. Moreover, for moderate sample sizes the bias has always to be taken into account and a superiority of one of the three methods can not be established in general. In the examples presented in Section 3 we observed a much better performance of the test based on \( T_N^{(1)} \).

2.5 Generalizations: Different bandwidths, smoothing techniques and random design

Remark 2.6. Note that we have assumed the equality of all bandwidths in Section 2.1 - 2.3, which substantially simplifies the presentation of the asymptotic results and their proofs. Nevertheless in practice it is strictly recommended to choose the bandwidths \( h_i (i = 1, \ldots, k) \) and \( h \) of each estimator \( \hat{g}_i \) and \( \hat{g} \) according to the size of the corresponding sample. If there exist constants \( b_1, \ldots, b_k \in (0, 1) \) such that these bandwidths satisfy (2.7) and

\[
(2.34) \quad \frac{h_i}{h} = b_i + O\left(\frac{1}{N}\right), \quad i = 1, \ldots, k
\]

as \( N \to \infty \), similar results as given in Theorem 2.1 - 2.3 can be established, where the constants \( B_k^{(i)} \) and \( D_k^{(i)} \) additionally depend on the proportions \( b_1, \ldots, b_k \) (note that \( B_k^{(3)} \) does not vanish in this case). For more details we refer to Neumeyer (1999) and Dette and Neumeyer (1999).

Remark 2.7. It should also be pointed out that the asymptotic results given in Theorem 2.1 - 2.3 do not depend on the special structures of the smoothing procedures used in the construction of the variance estimators. We used the Nadaraya-Watson estimator for the calculation of residuals because for this choice the proofs given in the appendix are more transparent. For example, a local polynomial estimator [see Fan (1992) or Fan and Gijbels (1996)] can be treated in the same way with greater mathematical complexity but without changing the structure of the asymptotic results. Although local polynomial estimators have various advantages for the estimation of the regression function, particularly at the boundaries, our simulation results showed that this superiority is not reflected in the problem of testing the equality of regression functions. A heuristic explanation of this observation is that the methods presented in Section 2.1 - 2.3 essentially avoid the direct estimation of the regression function and only use estimates for quantities smoothed by linear integral operators. Nevertheless there are still theoretical advantages of using local smoothing in the definition of the statistics \( T_N^{(i)} (i = 1, 2, 3) \). On the one hand the use of these estimators allows weaker assumptions on the design densities, because only the continuity of the design density is required (for local
polynomials of of odd order). On the other hand the bias of local polynomials of odd order is the same for all curves irrespective of the design pattern. More precisely, if equal bandwidths are used for the local polynomial estimation of the individual regression functions [see (2.4) and (2.6)] the terms $B_k^{(1)}$ and $B_k^{(2)}$ in Theorem 2.1 and 2.2 vanish, while the kernel $K$ in the asymptotic bias $D_k^{(i)}$ and in asymptotic variance $\beta_k^{(i)} (i = 1, 2, 3)$ of Theorem 2.1 - 2.3 has to be replaced by the equivalent higher order kernel corresponding to the local polynomial estimator [see Wand and Jones (1995)]. A similar observation was made by Alcalà, Christóbal and González Manteiga (1999) in the context of testing for a parametric form of the regression function.

**Remark 2.8.** The test statistics $T_N^{(1)}$, $T_N^{(2)}$ and $T_N^{(3)}$ can be directly used for a multivariate predictor and a random design. Under the assumption of a random design $t_{i1}, \ldots, t_{in}$ are realizations of i.i.d. random variables $T_{i1}, \ldots, T_{in}$ with positive density $r_i$ on the interval $[0,1]$ $(i = 1, \ldots, n)$. In this case the first parts of the statements of Theorem 2.1 - 2.3 regarding the asymptotic behaviour of the statistics and the hypothesis of equal regression functions remain valid and consistent tests are obtained exactly as in the case of a fixed design. However, it is worthwhile to mention that under the alternative a different asymptotic variance is obtained in all three cases. Consider for example the situation of Theorem 2.1 in the case of $k = 2$ independent random samples. Under a fixed alternative the asymptotic variance of the statistic $T_N^{(1)}$ is given by

$$
\text{Var}(T_N^{(1)}) = \frac{4\kappa_1\kappa_2}{N} \int (g_1 - g_2)^2(t) (\kappa_2 r_2(t) \sigma_2^2(t) + \kappa_1 r_1(t) \sigma_2^2(t)) \frac{r_1(t) r_2(t)}{(\kappa_1 r_1 + \kappa_2 r_2)^2(t)} dt
$$

$$+ \frac{\kappa_1\kappa_2}{N} \text{Var} \left( (g_1 - g_2)^2(T_{11}) \frac{\kappa_1^2 r_1^2(T_{11})}{(\kappa_1 r_1 + \kappa_2 r_2)^2(T_{11})} \right)
$$

$$+ \frac{\kappa_1^2\kappa_2}{N} \text{Var} \left( (g_1 - g_2)^2(T_{21}) \frac{\kappa_1^2 r_1^2(T_{21})}{(\kappa_1 r_1 + \kappa_2 r_2)^2(T_{21})} \right) + o\left( \frac{1}{N} \right).
$$

### 3 Simulation results

In similar problems it was observed by several authors [see e.g. Azzalini and Bowman (1993), Hjellvik and Tjøstheim (1995) or Alcalà, Christóbal and González Manteiga (1999)] that the asymptotic normal distribution under the null hypothesis does not provide a satisfactory approximation of the distribution of the statistics $T_N^{(i)}$ for reasonable sample sizes. For these reasons many authors propose the application of bootstrap procedures in these problems [see e.g. Hall and Hart (1990) or Härdle and Mammen (1993)]. In this section we study the finite sample performance of a wild bootstrap version of the test (2.24) and compare its power properties with several other procedures suggested in the literature. Some remarks regarding the consistency of this procedure are given in Section 4.4 of the appendix.

Because all simulation results published so far consider the two sample case with equal homoscedastic variance (i.e. $\sigma_1^2(t) = \sigma_2^2(t) = \sigma^2$), and we are interested in a comparison, we mainly restrict our study to this case. Moreover we will concentrate on the statistic $T_N^{(1)}$ based on the difference of variance estimators, because it performed better than $T_N^{(2)}$ (see Section 3.2) and it does not require the specification of a weight function (in contrast to the statistic $T_N^{(3)}$). In our study we used in fact an asymptotic equivalent test statistic given by

$$
\tilde{T}_N = \sigma^2 - \frac{n_1^2}{N \nu_1} \hat{\sigma}_1^2 - \frac{n_2^2}{N \nu_2} \hat{\sigma}_2^2
$$

12
where $n_1/n_2$, $n_2/n_2$ are normalizing constants converging to 1, such that $\hat{\sigma}_i^2$ is unbiased for constant regression $g_k$ [see Hall and Marron (1990)]. More precisely, these constants are defined by 

$$
\nu_\ell = n_\ell - 2 \sum_{i=1}^{n_\ell} u_{ii}^{(\ell)} + \sum_{i,k=1}^{n_\ell} (w_{ik}^{(\ell)})^2, \quad \ell = 1, 2,
$$

where 

$$
w_{ik}^{(\ell)} = \frac{K(\frac{u_{ik} - u_{ik}}{h_\ell})}{\sum_{i=1}^{n_\ell} K(\frac{u_{ik} - u_{ik}}{h_\ell})}, \quad \ell = 1, 2.
$$

We used the common wild bootstrap of residuals based on a nonparametric fit [see Härdle and Mammen (1993)]

$$
(\hat{\varepsilon}_{ij} = y_{ij} - \hat{g}(t_{ij}), \quad j = 1, \ldots, n_j; \quad i = 1, 2,
$$

where $\hat{g}$ is the estimator of the regression curve from the total sample defined in (2.6). Let $V_{ij}^*$ ($i = 1, 2, j = 1, \ldots, n_j$) denote i.i.d. random variables with masses $(\sqrt{5} + 1)/2\sqrt{5}$ and $(\sqrt{5} - 1)/2\sqrt{5}$ at the points $(1 - \sqrt{5})/2$ and $(1 + \sqrt{5})/2$ (note that this distribution satisfies $E[V_{ij}^*] = 0, E[V_{ij}^*]^2 = E[V_{ij}^*]^2] = 1$). Finally define $\varepsilon_{ij}^* = V_{ij}^* \hat{\varepsilon}_{ij}$ and the bootstrap sample by

$$
Y_{ij}^* = \hat{g}(t_{ij}) + \varepsilon_{ij}^*, \quad j = 1, \ldots, n_j; \quad i = 1, 2.
$$

For the test at level $\alpha$ the null hypothesis is rejected if $\hat{T}_N^*$ is bigger than the corresponding quantile of the bootstrap distribution of $\hat{T}_N$, i.e.

$$
(\hat{T}_N^* > \hat{T}_{N,\alpha}^{\alpha} | B[1 - \alpha]),
$$

where $\hat{T}_{N,\alpha}^{\alpha}$ denotes the $\alpha$th order statistic of the bootstrap sample $\hat{T}_{N,1}, \ldots, \hat{T}_{N,B}$. In our study we resampled $B = 200$ times and used 1000 simulations for the calculation of the level and power in each scenario. Moreover, we used the same bandwidth for the generation of the bootstrap sample (3.1) and the definition of the test statistic $\hat{T}_N$. The consistency of this procedure is indicated in Section 4.4.

We considered two samples at the design points

$$
t_{1i} = \frac{i - 1}{n_1 - 1}, \quad i = 1, \ldots, n_1
$$

$$
t_{2j} = \frac{j}{n_2}, \quad j = 1, \ldots, n_2
$$

and normally distributed errors in both samples unless it is stated otherwise, i.e.

$$
(\varepsilon_{1i}, \varepsilon_{2j}) \sim \mathcal{N}(0, \sigma^2).
$$

The kernel was chosen as $K(x) = \frac{3}{4}(1 - x^2)I_{[-1,1]}(x)$ (which yields $r = 2$) and the bandwidths are

$$
h_i = \left(\int_0^1 \sigma_i^2(t)dt \right)^{3/10} = \left(\frac{\sigma_i^2}{n_i}\right)^{3/10}, \quad i = 1, 2
$$

$$
h = \left(\frac{n_1 \int_0^1 \sigma_1^2(t)dt + n_2 \int_0^1 \sigma_2^2(t)dt}{n_1 + n_2}\right)^{3/10} = \left(\frac{\sigma_i^2}{n_1 + n_2}\right)^{3/10}
$$
where the last equalities follow in the case of homoscedasticity and \( \sigma_1^2 = \sigma_2^2 \). Note that we use different bandwidths for the estimators \( \hat{\gamma} \), \( \hat{g}_1 \) and \( \hat{g}_2 \) in our study.

**Table 3.1.** Simulated level of the test (3.3) for various sample sizes and standard normal errors. The designs are uniform [according to (3.4)] and \( g_1(t) = g_2(t) = t^2 \).

### 3.1 Simulation of the level

Our first example investigates the approximation of the level by the wild bootstrap version of the test (2.24). Firstly we considered quadratic regression functions \( g_1(t) = g_2(t) = t^2 \), standard normal distributed errors and different sample sizes \( n_1, n_2 = 10, 20, 30, 50 \). The results are summarized in Table 3.1 which shows the simulated rejection probabilities of the wild bootstrap test with level 10%, 5% and 2.5%. Our second Table 3.2 shows the corresponding results for the regression functions \( g_1(t) = g_2(t) = \cos(\pi t) \). We observe a reasonable approximation of the level by the wild bootstrap procedure in all cases, even in the case of very small samples [see also Hall and Hart (1990), who obtained a similar conclusion for their resampling procedure]. Note that for the more oscillating regression functions \( g_1(t) = \cos(\pi t) \) the approximation is slightly worse compared to the more smooth case \( g_1(t) = g_2(t) = t^2 \), which can be partially explained by a larger bias in the variance estimators \( \hat{\sigma}^2, \hat{\sigma}_1^2 \) and \( \hat{\sigma}_2^2 \).

**Table 3.2.** Simulated level of the test (3.3) for various sample sizes and standard normal errors. The designs are uniform [according to (3.4)] and \( g_1(t) = g_2(t) = \cos(\pi t) \).
As pointed out by a referee it might be of interest to investigate the approximation of the level under a heteroscedastic error distribution. To this end we considered the quadratic regression functions 

\[ g_1(t) = g_2(t) = t^2 \]

and the variance functions

\[
\begin{align*}
\sigma_1^2(t) &= \sigma_2^2(t) = \frac{e^t}{\int_0^1 e^x \, dx}, \\
\sigma_1^2(t) &= \frac{e^t}{\int_0^1 e^x \, dx}, \quad \sigma_2^2(t) = \frac{e^{2t}}{\int_0^1 e^{2x} \, dx},
\end{align*}
\]

where the first and second scenario correspond to the case of equal and unequal variance functions, respectively, and we normalized such that \( \int_0^1 \sigma_i^2(t) \, dt = 1 \) ( \( i = 1, 2 \)). The results are listed in Table 3.3 and 3.4 and demonstrate an excellent performance of the wild bootstrap procedure under heteroscedasticity.

3.2 The test of Kulasekera and Wang (1997)

Recently Kulasekera (1995) proposed a new testing procedure for the hypothesis (1.2) in the case of two samples with homoscedastic errors. Because this test is applicable for different designs in both groups and can detect alternatives converging to the null at a rate \(1/\sqrt{n}\), we will discuss it in a little more detail. The test is based on the quasi residuals

\[
e_{ii} = Y_{ii} - \hat{g}_i(t_{ii}), \quad i = 1, \ldots, n_1
\]

\[
e_{2j} = Y_{2j} - \hat{g}_j(t_{2j}), \quad j = 1, \ldots, n_2
\]

and the corresponding partial sums

\[
\mu_i(t) = \sum_{j=1}^{n_i} \frac{e_{ij}}{\sqrt{n_i}}, \quad 0 < t < 1; \quad i = 1, 2.
\]

The test statistic proposed by Kulasekera (1995) is defined as suitable function of

\[
K_1^{(i)} = \frac{1}{n_i S_{n_i}^2} \sum_{k=1}^{n_i} \mu_i^2(t), \quad i = 1, 2
\]

or

\[
K_2^{(i)} = \frac{1}{S_{n_i}^2} \int_0^1 \mu_i^2(t) d\mu_i(t), \quad i = 1, 2
\]

where \(S_{n_i}^2\) is a consistent estimator of \(\sigma_i^2 (i = 1, 2)\). Note that this test does not require equal designs in both groups. Kulasekera and Wang (1997) investigated the functions \(W_1 = \min\{K_1^{(1)}, K_1^{(2)}\}\), \(W_2 = \min\{|K_2^{(1)}|, |K_2^{(2)}|\}\) and proposed a method for choosing the bandwidth, which roughly speaking, maximizes the power at a specific alternative. As pointed out in the latter paper the data-based smoothing parameters inflate the size of the test and the discrepancy from the actual size depends largely on the variability of the reponses and the sample size. For these reasons Kulasekera and Wang (1997) used simulation (for \(g_1 = g_2 = 0\)) for finding the critical points.

In Table 3.5 we compare the test (3.3) with the procedure proposed by Kulasekera and Wang (1997). For the sake of comparison we chose the setup considered in Table 3 of the latter paper, that is normally distributed errors with variance \(\sigma^2 = 0.5\) and the following regression functions

\[
(a) \quad g_1(x) = -g_2(x) = 0.5 \cos(2\pi x)
\]

\[
(b) \quad g_1(x) = -g_2(x) = 0.5 \sin(2\pi x)
\]

\[
(c) \quad g_1(x) = g_2(x) - x = \cos(\pi x)
\]

\[
(d) \quad g_1(x) = g_2(x) - 1 = \cos(\pi x)
\]

\[
(e) \quad g_1(x) = g_2(x) - x = \cos(2\pi x)
\]

\[
(f) \quad g_1(x) = g_2(x) - 1 = \cos(2\pi x).
\]

Comparing the results of Table 3.5 with the corresponding results of Kulasekera and Wang’s (1997) in Table 3 of their paper we observe that the test proposed in this paper yields a substantial improvement with respect to the power in all considered cases. Note that Kulasekera and Wang (1997) chose the bandwidths such that the power is maximized (at the cost of a simulated level) and we could obtain a further improvement in power for the test (3.3) by applying a similar technique. Although
this would have theoretical advantages, we do not recommend this approach in practice, because this
data based choice of the smoothing parameter usually yields a large discrepancy between the size of
the test and the actual level.

Table 3.5. Simulated rejection probabilities of the test (3.3) for various alternatives given in (3.10). The designs are uniform according to (3.4) and the errors are normal with variance \( \sigma^2 = 0.5 \).

We remark that the test (3.3) can only detect alternatives converging to the null at a rate \( (N\sqrt{h})^{-1/2} \) [which gives \( N^{-1/30} \) for the choice (3.7)], while Kulasekera and Wang's (1997) test achieves the parametric rate \( N^{-1/2} \). On a first glance this is a contradiction to the results obtained in our simulation. However, these observations can be explained by the fact that the method of the lastnamed authors implicitly uses a sample splitting. One sample is used for estimating the regression while the other sample is used for the calculation of the residuals.

For the sake of comparison we also studied the performance of the test of Young and Bowman (1995) in this situation. The results are listed in Table 3.6. We observe a larger power of the test (3.3) based on the differences of variance estimators in most cases.

Table 3.6. Simulated rejection probabilities for the test of Young and Bowman (1995) for various alternatives given in (3.10). The designs are uniform according to (3.4) and the errors normal with variance \( \sigma^2 = 0.5 \).
3.3 The tests of Delgado (1993) and Dette and Munk (1998)

The test recently proposed by Dette and Munk (1998) was the first procedure which was applicable in the general model (1.1). This test is based on a simple estimate of an $L^2$-distance between the regression functions which does not depend on a smoothing parameter. Although this procedure can only detect alternatives which converge to the null at a rate of $N^{-1/4}$, the test has promising finite sample properties with respect to the quality of approximation of the level [see Dette and Munk (1998)]. Moreover, a comparison with Delgado’s (1993) test, which can detect alternatives converging to the null at a rate $N^{-1/2}$, indicates that for realistic sample sizes this test is comparable with procedures which are efficient from an asymptotic point of view. Delgado’s (1993) test requires equal design points and is based on the sup-norm of a marked empirical process of the pairwise differences from both samples.

In order to compare the new test (3.3) with these procedures we considered the setup given in Section 4.2 of Dette and Munk (1998), i.e. $n_1 = n_2 = 15$, $(g_i - g_1)(t) = 1$, $(g_i - g_2)(t) = \sin(2\pi t)$ and three types of error distributions [see also Hall and Hart (1990)]

\[
\begin{align*}
(i) & \quad N_{1, \mathcal{N}_2} \\
(ii) & \quad N_{\sqrt{2/\pi}, |\mathcal{N}_2| - \sqrt{2/\pi}} \\
(iii) & \quad N_{\sqrt{2/\pi}, \sqrt{2/\pi} - |\mathcal{N}_2|}.
\end{align*}
\]

The results are listed in Table 3.7 and a comparison of the power at the 5% level shows the following. While Delgado’s (1993) test performs better for the smooth alternative $g_1 - g_2 \equiv 1$, Dette and Munk’s (1998) test is more efficient for the oscillating alternative. The new test (3.3) has a reasonable performance in both cases. On the one hand it is substantially more powerful as Delgado’s test for the oscillating alternative and as Dette and Munk’s test for the smooth alternative. On the other hand it is comparable with these procedures in the remaining cases.

Table 3.7. Simulated rejection probabilities of the test (3.3) in the scenario considered by Dette and Munk (1998) Section 4.2. The design is uniform [according to (3.4)] and the error distributions are given by (3.11).

Our final example compares the new test with the bootstrap test introduced by Hall and Hart (1990). These authors mainly considered the case of equal design points and briefly mentioned a generalization of their approach to the general case. However, Kulasekera (1995) observed that this generalization is not reliable and recommends the application of Hall and Hart’s test only in the case of equal designs. Note that this test can detect alternatives converging to the null at a rate $N^{-1/2}$. 

For a comparison with our test we chose the setup of Table 3 in Hall and Hart (1990). The test proposed by these authors depends on a smoothing parameter $p$ and Table 3 in Hall and Hart (1990) lists results for three choices of $p$. More precisely the errors are given by (3.11) and the alternatives by $g_1 - g_2 = 1$ and $(g - g_2)(x) = x$ where $g_2 = 0$. The results are given in Table 3.8 and show that the new test is a serious competitor. In most cases we observe a better power for the new test (3.3), even if we compare it with the best choice of $p$ in the procedure of Hall and Hart.

4 Appendix: Proofs

4.1 Preliminaries

We will restrict ourselves to a proof of Theorem 2.1 in the case of $k = 2$ regression functions. The general case $k \geq 3$ and the asymptotic results given in Theorem 2.2 and 2.3 for $T_N^{(2)}$ and $T_N^{(3)}$ follow by exactly the same arguments with an additional amount of algebra and notation. For the sake of a transparent notation we will omit all indices referring to the number of samples and to the specific statistic discussed in Section 2. In other words we write $B$ instead of $B_k^{(1)}$, $T_N$ instead of $T_N^{(1)}$ etc.

Recalling the definition of the weights

$$w_{jk}^{(i)} = \frac{K(t_{ij} - t_{ik})}{\sum_{l=1}^{n_i} K(t_{ij} - t_{il})}, \quad i = 1, 2,$$

the Nadarya-Watson estimators (2.4) of the individual regression functions evaluated at the points $t_{ij}$ can be rewritten as

$$\hat{g}_i(t_{ij}) = \sum_{k=1}^{n_i} w_{jk}^{(i)} Y_{ik}, \quad i = 1, 2.$$
In order to obtain a similar representation for the estimator in the combined sample define the weights
\begin{equation}
(4.2) \quad w_{k,ij} = \frac{\int_0^1 K\left(\frac{t_i - t_{ij}}{h}\right) dt}{\sum_{l=1}^r \sum_{k=1}^m K\left(\frac{t_{ij} - t_{ij}}{h}\right)}. \nonumber
\end{equation}

The Nadaraya Watson estimator (2.6) evaluated at the points \( t_{ij} \) using the total sample can now be written as
\begin{equation}
(4.3) \quad \hat{g}(t_{ij}) = \sum_{l=1}^2 \sum_{k=1}^m w_{k,ij} y_{lk}. \nonumber
\end{equation}

We finally introduce the notation, \( \lambda_1 = \kappa_1 / \kappa_2 \) and
\begin{equation}
(4.4) \quad \rho(t) = r_1(t) + \frac{1}{\lambda_1} r_2(t) = \frac{1}{\kappa_1} [\kappa_1 r_1(t) + \kappa_2 r_2(t)] \nonumber
\end{equation}

which will be used frequently throughout this section. Our first result establishes the asymptotic expansion for the bias of the estimator \( T^{(1)}_N \).

**Lemma 4.0.** Assume that (2.1), (2.2), (2.3), (2.5), (2.7) are satisfied, then
\begin{equation}
(4.5) \quad E[\hat{\sigma}^2] = \int_0^1 \sigma^2_1(t) r_1(t) dt + d_i h^{2r} + o(h^{2r}) + O\left(\frac{1}{N_i}\right) \nonumber
\end{equation}

\[ + \frac{1}{N_i h} \left[ \int_{-1}^1 K^2(u) du - 2K(0) \right] \int_0^1 \sigma_2^2(t) dt \]

where the constant \( d_i \) is defined by
\[ d_i = k_i^2 \int_0^1 [(r_1(t) r_1\tau(t) - r_1\tau(t)]^2 \frac{1}{r_1(t)} dt \]

\((i = 1, \ldots, l)\). Moreover, if the null hypothesis of equal regression functions is valid we have for the estimator (2.9) in the case \( k = 2 \)
\begin{equation}
(4.6) \quad E[\hat{\sigma}^2] = \kappa_1 \int_0^1 \sigma_1^2(t) r_1(t) dt + \kappa_2 \int_0^1 \sigma_2^2(t) r_2(t) dt \nonumber
\end{equation}

\[ + \frac{1}{Nh} \left[ \int_{-1}^1 K^2(u) du - 2K(0) \right] \int_0^1 \sigma_2^2(t) \kappa_1 r_1(t) + \sigma_2^2(t) \kappa_2 r_2(t) \frac{dt}{(\kappa_1 r_1 + \kappa_2 r_2)(t)} \]

\[ + Ch^{2r} + o(h^{2r}) + O\left(\frac{1}{N}\right), \]

where the constant \( C \) is defined by
\[ C = k_i^2 \int_0^1 \left[ (g_1(\kappa_1 r_1 + \kappa_2 r_2)(t) - g_1(\kappa_1 r_1 + \kappa_2 r_2)(t))^2 \frac{dt}{(\kappa_1 r_1 + \kappa_2 r_2)(t)} \right]. \nonumber
\]

Under the alternative we obtain for the estimator (2.9) in the case \( k = 2 \)
\begin{equation}
(4.7) \quad E[\hat{\sigma}^2] = \kappa_1 \int_0^1 \sigma_1^2(t) r_1(t) dt + \kappa_2 \int_0^1 \sigma_2^2(t) r_2(t) dt + M^2 + O(h^{2r}) + O\left(\frac{1}{Nh}\right) \nonumber
\end{equation}
where the constant $M^2$ is defined by

\begin{equation}
M^2 = \kappa_1 \kappa_2 \int_0^1 (g_1(t) - g_2(t))^2 \frac{r_1(t)r_2(t)}{\kappa_1 r_1(t) + \kappa_2 r_2(t)} \, dt.
\end{equation}

**Proof of Lemma 4.0.** The first part (4.5) of the Lemma is obtained from the representation (4.6) by considering equal variance functions and design densities. The proof of (4.6) and (4.7) essentially follows the arguments of Hall and Marron (1990) and we will only mention the main modifications here, which take into account the mixture of two design densities. Define

\begin{equation}
\Delta_{ij} = g_i(t_{ij}) - \sum_{l=1}^{n_i} \sum_{k=1}^{m} w_{l,k} g_l(t_k)
\end{equation}

then the expectation of the variance estimator (2.9) from the total sample splits into two parts, i.e.

\begin{equation}
E[\hat{\sigma}^2] = \frac{1}{N} \sum_{i=1}^{n} \sum_{j=1}^{n_i} \Delta_{ij}^2 + \frac{1}{N} \sum_{i=1}^{n} \sum_{j=1}^{n_i} E \left[ (\sigma_i(t_{ij}) \varepsilon_{ij} - \sum_{l=1}^{n_i} \sum_{k=1}^{m} w_{l,k} \sigma_l(t_k) \varepsilon_{ik})^2 \right].
\end{equation}

A straightforward but tedious calculation shows

\begin{equation}
\Delta_{ij} = \frac{1}{\rho(t_{ij})} + R(t_{ij}) \left[ \frac{\kappa_2}{\kappa_i} r_{3/3}(t_{ij}) (g_i - g_{3/3})(t_{ij}) + \frac{1}{h} \int K\left( \frac{t_{ij} - t}{h} \right) \left( (g_1r_1)(t_{ij}) - (g_1r_1)(t) + g_i(t_i) \{ \rho(t) - \rho(t_{ij}) \} \right) dt \right] + O\left( \frac{1}{Nh} \right) + O(h^{2r})
\end{equation}

\begin{equation}
\frac{\kappa_2}{\kappa_i} r_{3/3}(t_{ij}) (g_i - g_{3/3})(t_{ij}) + O(h^r) + O\left( \frac{1}{Nh} \right),
\end{equation}

uniformly in $j = 1, \ldots, n_i, i = 1, 2$. Here the function $R$ is defined by

\begin{equation}
R(x) = \frac{\rho(x) - \int K\left( \frac{x - t}{h} \right) \rho(t) \, dt}{\rho^3(x)} = O(h^r),
\end{equation}

where the estimate on the right hand side follows from the differentiability of the design densities and the moment assumptions on the kernel.

Now the evaluation of the first term in (4.10) gives for $g_1 \neq g_2$

\begin{equation}
\frac{1}{N} \sum_{i=1}^{n} \sum_{j=1}^{n_i} \Delta_{ij}^2 = \kappa_1 \int_0^1 \left( \frac{1}{\lambda_1} r_2(x) r_1(x) \right) \rho^2(x) \, dx + \kappa_2 \int_0^1 \left( \frac{1}{\rho^2(x)} \right) (g_1 - g_2)^2(x) \, dx + 2 \kappa_2 \int_0^1 \left( \frac{1}{\lambda_1} r_2(x) r_1(x) \right) (g_1 - g_2)(x) \left( \frac{1}{h} \int K\left( \frac{x - t}{h} \right) \left( (g_1r_1)(x) - (g_1r_1)(t) + g_1(x)(\rho(t) - \rho(x)) + \left( g_2 \frac{1}{\lambda_1} r_2(x) \right) \right) \, dt \right) \, dx
\end{equation}

21
\[ + 2 \kappa_1 \int_0^1 \frac{R(x)}{\rho(x)} \left( \frac{1}{\lambda_1} r_2(x)(g_1 - g_2)(x) \right)^2 r_1(x) \, dx \]
\[ + 2 \kappa_2 \int_0^1 \frac{r_2(x)r_1(x)}{\rho^2(x)} (g_2 - g_1)(x) \left( \frac{1}{h} \int K\left( \frac{x - t}{h} \right) \left\{ (g_1 r_1)(x) - (g_1 r_1)(t) + g_1(x)(\rho(t) - \rho(x)) + \left( \frac{1}{\lambda_1} r_2 \right)(x) - (g_2 \frac{1}{\lambda_1} r_2)(t) - (g_1 r_1)(x) + (g r_1)(t) - g_2(x)(\rho(t) - \rho(x)) - (g_2 \frac{1}{\lambda_1} r_2)(x) + \left( \frac{1}{\lambda_1} r_2 \right)(t) \right\} \, dt \right) \, dx \]
\[ + 2 \kappa_2 \int_0^1 \frac{R(x)}{\rho(x)} (g_1 - g_2)^2(x) r_1(x) \frac{1}{\lambda_1} r_2(x) \, dx + O(h^{2\nu}) + O\left( \frac{1}{N h} \right) \]
\[ = \kappa_1 \int_0^1 \frac{1}{\lambda_1} r_2(x)r_1(x) (g_1 - g_2)^2(x) \rho(x) \, dx + 2 \kappa_2 \int_0^1 \frac{1}{\lambda_1} r_2(x)r_1(x) \rho^2(x) (g_1 - g_2)(x) \left( \frac{1}{h} \int K\left( \frac{x - t}{h} \right) (g_1(x) - g_2(x))(\rho(t) - \rho(x)) \, dt \right) \, dx \]
\[ + 2 \kappa_2 \int_0^1 \frac{R(x)}{\rho(x)} (g_1 - g_2)^2(x) r_1(x) \frac{1}{\lambda_1} r_2(x) \, dx + O(h^{2\nu}) + O\left( \frac{1}{N h} \right) \]
\[ = \kappa_1 \int_0^1 \frac{1}{\lambda_1} r_2(x)r_1(x) (g_1 - g_2)^2(x) \rho(x) \, dx + O(h^{2\nu}) + O\left( \frac{1}{N h} \right) \]
\[ = M^2 + O(h^{2\nu}) + O\left( \frac{1}{N h} \right), \]

where we used the definition of \( 1/\lambda_1 = \kappa_2/\kappa_1 \) in the first equality, the definition of \( R(x) \) in (4.13) and of \( M^2 \) in (4.8) for the last step. Under the assumption of equal regression curves \( g_1 = g_2 \) (4.11) simplifies and we obtain observing (2.7) and (4.4)

\[ \frac{1}{N} \sum_{i=1}^n \sum_{j=1}^n \Delta_{ij}^2 = \kappa_1 \int_0^1 \left[ \frac{1}{\rho(x)} + R(x) \right]^2 \left( \frac{1}{h} \int K\left( \frac{x - t}{h} \right) \left\{ (g_1 \rho)(x) - (g_1 \rho)(t) + g_1(x)(\rho(t) - \rho(x)) \right\} \, dt + O\left( \frac{1}{N h} \right) \right)^2 r_1(x) \, dx \]
\[ + \kappa_1 \int_0^1 \left[ \frac{1}{\rho(x)} + R(x) \right]^2 \left( \frac{1}{h} \int K\left( \frac{x - t}{h} \right) \left\{ (g_1 \rho)(x) - (g_1 \rho)(t) + g_1(x)(\rho(t) - \rho(x)) \right\} \, dt + O\left( \frac{1}{N h} \right) \right)^2 \frac{1}{\lambda_1} r_2(x) \, dx + O\left( \frac{1}{N} \right) \]
\[ = \kappa_i \int_0^1 \left[ \frac{1}{\rho(x)} + R(x) \right]^2 \rho(x) \left\{ h^r k_c \left[ g_i \rho^{(r)} - (g_i \rho)^{(r)} \right] (x) + o(h^r) + O \left( \frac{1}{Nh} \right) \right\} \, dx \\
\quad + O \left( \frac{1}{N} \right) \]
\[ = h^{2r} k_c^2 \kappa_i \int_0^1 \frac{1}{\rho(x)} \left[ g_i \rho^{(r)} - (g_i \rho)^{(r)} \right]^2 (x) \, dx + o(h^{2r}) + O \left( \frac{1}{N} \right) \]
\[ = h^{2r} C + o(h^{2r}) + O \left( \frac{1}{N} \right) \]
\[(4.15)\]

For the second term in (4.10) we obtain by a straightforward but cumbersome calculation

\[ U = \frac{1}{N} \sum_{i=1}^N \sum_{j=1}^n E \left[ \left( \sigma_i(t_{ij}) \epsilon_{ij} - \sum_{l=1}^n \sum_{k=1}^n w_{ik,ij} \sigma_i(t_{ik}) \epsilon_{ik} \right)^2 \right] \]
\[ = \frac{1}{N} \sum_{i=1}^N \sum_{j=1}^n \sigma_i^2(t_{ij}) - \frac{2}{N} \sum_{i=1}^N \sum_{j=1}^n \sigma_i^2(t_{ij}) w_{ij,ij} + \frac{2}{N} \sum_{i=1}^N \sum_{j=1}^n \sum_{l=1}^n \sum_{k=1}^n \sigma_i^2(t_{ik}) w_{ik,ij}^2 \]
\[ = \sum_{i=1}^N \kappa_i \int_0^1 \sigma_i^2(t) r_i(t) \, dt \]
\[ + \frac{2}{N} \sum_{i=1}^N \frac{1}{Nh} \left[ -2K(0) \int_0^1 \sigma_i^2(t) \frac{\rho_{i1}(t)}{\rho(t)} \, dt + \frac{1}{h} \int \int K^2 (t - x) \frac{\sigma_i^2(x) \rho_{i1}(x)}{\rho(t)} \, dx \, dt \right] \]
\[ + O \left( \frac{1}{N} \right) + O \left( \frac{h^r}{Nh} \right) + O \left( \frac{1}{(Nh)^2} \right) \]
\[ = \kappa_1 \int_0^1 \sigma_1^2(t) r_1(t) \, dt + \kappa_2 \int_0^1 \sigma_2^2(t) r_2(t) \, dt \]
\[ + \frac{1}{Nh} \left\{ \int K^2(u) \, du - 2K(0) \right\} \left\{ \int_0^1 \frac{\sigma_1^2(x) r_1(x)}{\rho(x)} \, dx + \int_0^1 \frac{\sigma_2^2(x) r_2(x)}{\rho(x)} \, dx \right\} + O \left( \frac{1}{N} \right) \]

and the assertions (4.6) and (4.7) follow from (4.10), (4.14), (4.15) and (4.16).

\[ \square \]

### 4.2 Proof of Theorem 2.1: the null hypothesis of equal regression functions

In a first step we introduce the notation [observing (4.1)]

\[ \delta_{ij} = g_i(t_{ij}) - \sum_{k=1}^{n_i} \omega_{jk}^{(i)} g_i(t_{ik}), \quad j = 1, \ldots, n, \quad i = 1, 2 \]

and decompose the centered version of $T_N$ as follows

\[ T_N - E[T_N] = \sigma^2 - \frac{n_1}{N} \sigma_1^2 - \frac{n_2}{N} \sigma_2^2 - E[T_N] = R_{1,N} + R_{2,N} \]

\[ (4.18) \]
where

\[
R_{1,N} = \frac{2}{N} \sum_{i=1}^{n_i} \sum_{j=1}^{n_j} \Delta_{ij} \left( \sigma_i(t_{ij})\varepsilon_{ij} - \sum_{l=1}^{n} \sum_{k=1}^{n_k} w_{ik,ij}\sigma_l(t_{lk})\varepsilon_{lk} \right) \\
- \frac{2}{N} \sum_{i=1}^{n_i} \sum_{j=1}^{n_j} \delta_{ij} \left( \sigma_i(t_{ij})\varepsilon_{ij} - \sum_{k=1}^{n_k} w_{jk}^{(i)}\sigma_i(t_{ik})\varepsilon_{ik} \right) \\
= \hat{T}_N^{(1)} + \hat{T}_N^{(2)},
\]

\[
R_{2,N} = \frac{1}{N} \sum_{i=1}^{n_i} \sum_{j=1}^{n_j} \left( \sigma_i(t_{ij})\varepsilon_{ij} - \sum_{l=1}^{n} \sum_{k=1}^{n_k} w_{ik,ij}\sigma_l(t_{lk})\varepsilon_{lk} \right)^2 \\
- \frac{1}{N} \sum_{i=1}^{n_i} \sum_{j=1}^{n_j} E \left[ \left( \sigma_i(t_{ij})\varepsilon_{ij} - \sum_{l=1}^{n} \sum_{k=1}^{n_k} w_{ik,ij}\sigma_l(t_{lk})\varepsilon_{lk} \right)^2 \right] \\
- \frac{1}{N} \sum_{i=1}^{n_i} \sum_{j=1}^{n_j} \left( \sigma_i(t_{ij})\varepsilon_{ij} - \sum_{k=1}^{n_k} w_{jk}^{(i)}\sigma_i(t_{ik})\varepsilon_{ik} \right)^2 \\
+ \frac{1}{N} \sum_{i=1}^{n_i} \sum_{j=1}^{n_j} E \left[ \left( \sigma_i(t_{ij})\varepsilon_{ij} - \sum_{k=1}^{n_k} w_{jk}^{(i)}\sigma_i(t_{ik})\varepsilon_{ik} \right)^2 \right] \\
= \sum_{j=3}^{7} \hat{T}_N^{(j)}.
\]

Here the random variables \(\hat{T}_N^{(j)}\) are defined by

\[
\hat{T}_N^{(i)} = \frac{1}{N} \sum_{j=1}^{n_i} \alpha_{ij}\varepsilon_{ij}, \quad i = 1, 2
\]

\[
\hat{T}_N^{(2+i)} = \frac{1}{N} \sum_{j=1}^{n_i} k_{ij}(\varepsilon_{ij}^2 - 1), \quad i = 1, 2
\]

\[
\hat{T}_N^{(4+s)} = \frac{1}{N} \sum_{i=1}^{n_i} \sum_{l_{i,j} \neq i} r_{il}^{(s)}\varepsilon_{si}\varepsilon_{sl}, \quad s = 1, 2
\]

\[
\hat{T}_N^{(7)} = \frac{1}{N} \sum_{i=1}^{n_i} \sum_{j=1}^{n_j} \tilde{t}_{ij}\varepsilon_{1j}\varepsilon_{2j}
\]

and the coefficients \(\alpha_{ij}\) are given by

\[
\alpha_{ij} = 2 \left( \Delta_{ij} - \delta_{ij} - \sum_{l=1}^{n} \sum_{k=1}^{n_k} \Delta_{lk}w_{ij,lk} + \sum_{k=1}^{n_k} \delta_{lk}w_{ik}^{(i)} \right) \sigma_i(t_{ij})
\]

\((j = 1, \ldots, n_i; i = 1, 2)\) where \(\Delta_{ij}\) and \(\delta_{ij}\) are defined in (4.9) and (4.17), respectively. The coefficients \(k_{ij}, r_{il}^{(s)}, \tilde{t}_{ij}\) in the representation of \(R_{2,n}\) are defined as follows:

\[
k_{ij} = \left( 2w_{ij}^{(i)} - 2w_{ij,ij} + \sum_{l=1}^{2} \sum_{k=1}^{n_k} w_{ij,lk}^2 - \sum_{k=1}^{n_k} (w_{ik}^{(i)})^2 \right) \sigma_i^2(t_{ij}), \quad i = 1, 2,
\]
\begin{equation}
G(s) = \left(2w_{i0} - 2w_{n0,i} + \frac{2}{\pi} \sum_{j=1}^{n} \sum_{k=1}^{n} w_{jk,i}w_{jk,k} - \frac{1}{n} \sum_{k=1}^{n} w_{ki}^2 \right) \sigma_i \sigma_i(s), \quad s = 1, 2, \tag{4.27}
\end{equation}

\begin{equation}
\tilde{r}_{ij} = \left(-2w_{i2,j} - 2w_{2,i,j} + \frac{2}{\pi} \sum_{l=1}^{n} \sum_{k=1}^{n} w_{lk,i}w_{lk,k} \right) \sigma_l \sigma_i(t), \quad j = 1, 2, \tag{4.28}
\end{equation}

The next Lemmata specify the asymptotic behaviour of the terms \(\tilde{T}_N^{(j)}\) on the right hand side of (4.19) and (4.20). Note that all terms in these representations are centered, i.e. \(E[\tilde{T}_N^{(j)}] = 0\) (\(j = 1, \ldots, 7\)).

**Lemma 4.1.** If the assumptions of Theorem 2.1 are satisfied we have under the hypothesis of equal regression curves

\[ \tilde{T}_N^{(j)} \overset{\text{d}}{=} o_p\left(\frac{1}{N\sqrt{h}}\right), \quad j = 1, 2 \]

and under the alternative

\[ \text{Var}(\tilde{T}_N^{(i)}) = \frac{4}{N^2} \sum_{i=1}^{n_1} \alpha_{ii}^2 \frac{r_{i2}(t)}{\rho(t)} (g_1 - g_2)(t) - \frac{r_2^2(t)}{r_1(t)(\kappa_1 \rho(t) + \kappa_2 \rho_2(t))} dt + o\left(\frac{1}{N}\right), \quad i = 1, 2. \]

**Proof:** We only prove the assertion for the statistic \(\tilde{T}_N^{(1)}\), the remaining case follows by exactly the same arguments. From (4.21) it follows

\begin{equation}
\text{Var}(\tilde{T}_N^{(1)}) = \frac{1}{N^2} \sum_{i=1}^{n_1} \alpha_{ii}^2 \frac{r_{i2}(t)}{\rho(t)} (g_1 - g_2)(t), \tag{4.29}
\end{equation}

where, by (4.25) and (4.12)

\begin{equation}
\alpha_{ii} = 2 \left\{ \frac{1}{\kappa_1 \rho(t_i)} (g_1 - g_2)(t_i) \frac{r_{i2}(t_i)}{\rho(t_i)} \sum_{l=1}^{n} \sum_{k=1}^{n} \frac{\kappa_2 r_{23-1}(t_k)}{\rho(t_k)} (g_1 - g_2)(t_k) K \left( \kappa_1 \frac{t_k - t_i}{h} \right) \frac{1}{\rho(t_k)} \right\} \sigma_i(t_i) + O(h^r) + O\left(\frac{1}{N^2 h} \right)
\end{equation}

uniformly with respect to \(i = 1, \ldots, n_1\). The last equality in (4.30) uses the fact that the integral approximations of the two sums have the same absolute value with opposite signs. Now (4.29) implies under the hypothesis of equal regression curves

\[ \text{Var}(\tilde{T}_N^{(1)}) = o\left(\frac{1}{N^2 h}\right) \]

and an application of Chebysev’s inequality proves the first part of the Lemma. For the second part we obtain from (4.29) and (4.30)

\begin{equation}
\text{Var}(\tilde{T}_N^{(1)}) = \frac{1}{N^2} \sum_{i=1}^{n_1} \left( \frac{2}{\kappa_1 \rho(t_i)} (g_1 - g_2)(t_i) \frac{r_{i2}(t_i)}{\rho(t_i)} \sigma_i(t_i) \right)^2 + \frac{n_1}{N^2} O(h^r) + O\left(\frac{1}{N^2 h} \right)
\end{equation}

\[ = \frac{4}{N} \kappa_1 \int_0^1 (g_1 - g_2)^2(t) \sigma_i^2(t) \frac{r_1(t)(\frac{1}{\kappa_1 r_{i2}})^2(t)}{\rho^2(t)} dt + o\left(\frac{1}{N}\right), \quad i = 1, 2. \]
which completes the proof, by the definition of $\rho$ and $\lambda_i$.

\[\square\]

**Lemma 4.2.** Under the assumptions of Theorem 2.1 we have

\[
\hat{T}^{(j)}_N = o\left(\frac{1}{\sqrt{N}}\right), \quad j = 3, 4.
\]

**Proof.** Note that $E[\hat{T}^{(j)}_N] = 0$ for $j = 3, 4$. Recalling the definition of the coefficients $k_{ii}$ in (4.26) we obtain

\[
k_{ii} = \left\{ \frac{2K(0)}{n_1 h_1} \frac{1}{r_1(t_{ii})} - \frac{2K(0)}{n_1 h} \frac{1}{\rho(t_{ii})} + \frac{1}{n_1 h^2} \int K^2 \left( \frac{s - t_{ii}}{h} \right) \frac{1}{\rho(s)} \frac{d}{ds} \right\} \sigma_i^2(t_{ii}) + o\left(\frac{1}{n_1 h}\right) = O\left(\frac{1}{N h}\right)
\]

uniformly in $i = 1, \ldots, n_1$. This implies for the variance of $\hat{T}^{(3)}_N$

\[
\text{Var}(\hat{T}^{(3)}_N) = \frac{1}{N^2} \sum_{i=1}^{n_1} k_{ii} \text{Var}(z_{ii}) = o\left(\frac{1}{N^2 h}\right)
\]

and proves Lemma 4.2 for the case $j = 3$. The remaining case is obtained by exactly the same arguments and therefore omitted.

\[\square\]

**Lemma 4.3.** Under the assumptions of Theorem 2.1 we have

\[
\text{Var}(\hat{T}^{(4+i)}_N) = \frac{2}{N^2 h} \int_0^1 \sigma_i^2(x) \left[ 1 - \frac{r_i(x)}{\rho(x)} \right]^2 dx \cdot \int (2K - K* K)^2(u) du + o\left(\frac{1}{N^2 h}\right), \quad i = 1, 2.
\]

**Proof.** We only sketch a proof of the first part $i = 1$ of the assertion, the remaining case $i = 2$ follows by exactly the same arguments. Recalling the definition of the weights $r_{ii}^{(s)}$ in (4.27) we obtain by straightforward algebra

\[
r_{ii}^{(1)} = \left\{ \frac{2K \left( \frac{t_{ii} - t_{il}}{h} \right)}{r_1(t_{ii})} \frac{1}{r_1(t_{il})} - K \left( \frac{t_{ii} - t_{ll}}{h} \right) \frac{2}{\rho(t_{ii})} + \frac{1}{h} \int K \left( \frac{s - t_{ii}}{h} \right) K \left( \frac{s - t_{ll}}{h} \right) \frac{1}{\rho(s)} \frac{d}{ds} \right\} \sigma_i(t_{ii}) \sigma_i(t_{il}) + o\left(\frac{1}{N}\right)
\]

uniformly for $i, l = 1, \ldots, n_1$ and straightforward but tedious algebra shows
\[
\text{Var}(\hat{T}^{(3)}_N) = \frac{1}{N^2} \sum_{i=1}^{n_1} \sum_{j=1}^{n_2} (r_{ii}^{(1)})^2 + r_{ij}^{(1)} r_{ij}^{(1)} = \frac{2}{N^2} \sum_{i=1}^{n_1} \sum_{j=1}^{n_2} (r_{ii}^{(1)})^2 + \alpha \left( \frac{1}{N^2 h} \right)
\]

\[
= \frac{2}{N^2 h} \left\{ 4 \int K^2(u) \, du \int_{0}^{1} \sigma_1^4(x) \left[ 1 - \frac{r_1(x)}{\rho(x)} \right]^2 \, dx + \int (K * K)^2(u) \, du \int_{0}^{1} \sigma_1^4(x) \left[ 1 - \frac{r_1(x)}{\rho(x)} \right]^2 \, dx \right. \\
- 4 \int (K * K)(u)K(u) \, du \int_{0}^{1} \sigma_1^4(x) \left[ 1 - \frac{r_1(x)}{\rho(x)} \right]^2 \, dx \left. \right\} + o\left( \frac{1}{N^2 h} \right)
\]

\[
= \frac{2}{N^2 h} \int_{0}^{1} \sigma_1^4(x) \left[ 1 - \frac{r_1(x)}{\rho(x)} \right]^2 \cdot \int (2K - K * K)^2(u) \, du + o\left( \frac{1}{N^2 h} \right).
\]

**Lemma 4.4.** Under the assumptions of Theorem 2.1 we have

\[
\text{Var}(\hat{T}^{(7)}_N) = \frac{4}{N^2 h} \int (2K - K * K)^2(u) \, du \int_{0}^{1} \frac{r_1(x)}{\rho(x)} \frac{r_2(x)}{\rho^2(x)} \sigma_1^2(x) \sigma_2^2(x) \, dx + o\left( \frac{1}{N^2 h} \right).
\]

**Proof.** A straightforward calculation shows for the coefficients \( \bar{t}_{ij} \) in (4.28)

\[
(4.32) \quad \bar{t}_{ij} = \left\{ - \frac{2}{n_1 h} K \left( \frac{t_{ii} - t_{2j}}{h} \right) \left( \frac{1}{\rho(t_{ii})} + \frac{1}{\rho(t_{2j})} \right) \right.
\]

\[
+ \frac{2}{n_1 h^2} \int K \left( \frac{s - t_{ii}}{h} \right) K \left( \frac{s - t_{2j}}{h} \right) \frac{1}{\rho(s)} \, ds \left. \right\} \sigma_1(t_{ii}) \sigma_2(t_{2j}) + o\left( \frac{1}{N} \right)
\]

(uniformly for \( i = 1, \ldots, n_1 \), \( j = 1, \ldots, n_2 \)) which implies for the variance of \( \hat{T}^{(7)}_N \)

\[
\text{Var}(\hat{T}^{(7)}_N) = \frac{1}{N^2} \sum_{i=1}^{n_1} \sum_{j=1}^{n_2} \bar{t}_{ij}^2
\]

\[
= \frac{1}{N^2 h} \int \frac{r_1(x)}{\rho(x)} \frac{r_2(x)}{\rho^2(x)} \sigma_1^2(x) \sigma_2^2(x) \, dx \times \\
\left\{ 16 \int K^2(u) \, du - 16 \int (K * K)(u)K(u) \, du + 4 \int (K * K)^2(u) \, du \right\} + o\left( \frac{1}{N^2 h} \right)
\]

\[
= \frac{4}{N^2 h} \int (2K - K * K)^2(u) \, du \int_{0}^{1} \frac{r_1(x)}{\rho(x)} \frac{r_2(x)}{\rho^2(x)} \sigma_1^2(x) \sigma_2^2(x) \, dx + o\left( \frac{1}{N^2 h} \right).
\]

**Lemma 4.5.** Under the assumptions of Theorem 2.1 we have for the covariances of the statistics defined in (4.21) – (4.24)

\[
\text{Cov}(\hat{T}^{(i)}_N, \hat{T}^{(j)}_N) = 0, \quad \text{if } \{i, j\} \neq \{1, 3\}, \{2, 4\}.
\]

27
Under the hypothesis of equal regression functions it follows
\[
\text{Cov}(\hat{T}_N^{(1)}, \hat{T}_N^{(3)}) = o\left(\frac{1}{N^2h}\right), \quad \text{Cov}(\hat{T}_N^{(2)}, \hat{T}_N^{(4)}) = o\left(\frac{1}{N^2h}\right)
\]
while under the alternative \(g_1 \neq g_2\)
\[
\text{Cov}(\hat{T}_N^{(1)}, \hat{T}_N^{(3)}) = o\left(\frac{1}{N}\right), \quad \text{Cov}(\hat{T}_N^{(2)}, \hat{T}_N^{(4)}) = o\left(\frac{1}{N}\right).
\]

**Proof.** The first part of Lemma 4.5 is obvious. From (4.21) and (4.22) we obtain
\[
\text{Cov}(\hat{T}_N^{(1)}, \hat{T}_N^{(3)}) = \frac{1}{N^2} \sum_{i=1}^{n_1} \alpha_{1i} k_{1i} E[\varepsilon_{1i}^3]
\]
where \(\alpha_{1i}, k_{1i}\) are defined in (4.25) and (4.26), respectively. Now (4.30) gives
\[
\alpha_{1i} = \begin{cases} 
O(h^r) + O\left(\frac{1}{Nh}\right) & : \text{if } g_1 = g_2 \\
O(1) & : \text{if } g_1 \neq g_2
\end{cases}
\]
(uniformly for \(i = 1, \ldots, n_1\)). Similarly, we have from (4.31)
\[
k_{1i} = O\left(\frac{1}{Nh}\right),
\]
(uniformly for \(i = 1, \ldots, n_1\)) which implies
\[
\text{Cov}(\hat{T}_N^{(1)}, \hat{T}_N^{(3)}) = o\left(\frac{1}{N^2h}\right)
\]
under the null-hypothesis, and
\[
\text{Cov}(\hat{T}_N^{(1)}, \hat{T}_N^{(3)}) = o\left(\frac{1}{N}\right)
\]
under the alternative \(g_1 \neq g_2\). This proves the second part of the assertion for the statistics \(\hat{T}_N^{(1)}\) and \(\hat{T}_N^{(3)}\). The remaining case follows by exactly the same arguments and is therefore omitted.

**Proof of Theorem 2.1 (i):** Observing Lemma 4.0 and (2.7) we obtain
\[
N \sqrt{h} \left( T_N - Bh^{2r} - \frac{1}{Nh} D \right) = N \sqrt{h} \left( T_N - E[T_N] \right) + o(1)
\]
\[
= N \sqrt{h} \left( \hat{T}_N^{(5)} + \hat{T}_N^{(6)} + \hat{T}_N^{(7)} \right) + o_p(1),
\]
\[
= \sum_{s=1}^{2} \left[ \sum_{i=1}^{n_1} \sum_{j=1}^{n_2} \sqrt{h} r_{il}^{(s)} \varepsilon_{sl} \varepsilon_{sj} \right] + \sum_{i=1}^{n_1} \sum_{j=1}^{n_2} \sqrt{h} r_{ij}^{(s)} \varepsilon_{1i} \varepsilon_{2j} + o_p(1)
\]
where the second equality follows from (4.18), (4.19), (4.20), Lemma 4.1 – 4.5 and the constants B and D are defined in (2.10) for \(k = 2\). Defining
\[
\tilde{r}_{il}^{(s)} := \frac{r_{il}^{(s)} + r_{il}^{(s)}}{2}, \quad s = 1, 2;
\]

28
the right hand side of this equation can be written as a symmetric quadratic form with vanishing diagonal elements, i.e.

\[ W_N = N \sqrt{h} \left( \hat{T}_N^{(5)} + \hat{T}_N^{(6)} + \hat{T}_N^{(7)} \right) = X^T A X \]

where \( X = (X_1, \ldots, X_N)^T = (\varepsilon(1), \varepsilon(2))^T \), \( \varepsilon(i) = (\varepsilon_1, \ldots, \varepsilon_{m_k}) \) \( (i = 1, 2) \), the matrix \( A = (a_{ij})_{i,j=1,\ldots,N} \) is given by \( a_{ii} = 0 \) \( (i = 1, \ldots, N) \)

\[
a_{ij} := \begin{cases} 
\sqrt{\hat{r}^{(1)}_{ij}} & : i, j = 1, \ldots, n, i \neq j \\
\sqrt{\hat{r}^{(2)}_{i,j-n}} \sqrt{\hat{r}^{(3)}_{i-n,j}} & : i = 1, \ldots, n, j = n + 1, \ldots, n + n_2 \\
\sqrt{\hat{r}^{(3)}_{i-n,j}} & : i = n + 1, \ldots, n + n_2, j = 1, \ldots, n \\
\sqrt{\hat{r}^{(4)}_{i-j-n}} & : i, j = n + 1, \ldots, n + n_2, i \neq j 
\end{cases}
\]  

(4.33)

and \( \hat{r}_{ij}^{(k)} \) are defined in (4.27) and (4.28), respectively.

In order to show asymptotic normality of the statistic \( W_N \) under the hypothesis of equal regression curves we apply Theorem 5.2 in de Jong (1987). For the asymptotic variance of \( W_N \) we obtain from Lemma 4.3 - 4.5 and the definition of \( \rho \) in (4.4)

\[
\sigma^2_N = \text{Var}(N \sqrt{h} (\hat{T}_N^{(5)} + \hat{T}_N^{(6)} + \hat{T}_N^{(7)})) = \beta^2 + o(1) = O(1),
\]

where \( \beta^2 = \beta_{2,1}^2 \) is defined in (2.11) for \( k = 2 \). Observing (4.32) we have

\[
h \sum_{j=1}^{n_2} \hat{r}_{ij}^2 = \frac{1}{n_1} \left( \frac{4}{h} \int K^2 \left( \frac{t_{ii} - t}{h} \right) \left( \frac{1}{\rho(t_{ii})} + \frac{1}{\rho(t)} \right)^2 \sqrt{\lambda_1} r_2(t) dt \right) \\
+ \frac{4}{h^2} \int \left( \int K \left( \frac{s - t_{ii}}{h} \right) K \left( \frac{s - t}{h} \right) \frac{1}{\rho(s)} ds \right)^2 \sqrt{\lambda_1} r_2(t) \sigma^2_2(t) dt \\
+ \frac{8}{h^2} \int \left( \int K \left( \frac{t_{ii} - t}{h} \right) K \left( \frac{s - t_{ii}}{h} \right) K \left( \frac{s - t}{h} \right) \frac{1}{\rho(s)} \right) \sigma^2_2(t) dt \\
\times \left( \frac{1}{\rho(t_{ii})} + \frac{1}{\rho(t)} \right) \frac{1}{\rho(s)} ds dt \right) \sigma^2_2(t_{ii}) + o(1) = O(1)
\]

and a similar argument implies

\[
h \sum_{j=1}^{n_1} (\hat{r}_{ij}^{(1)})^2 = O(\frac{1}{N}).
\]

From these estimates it follows

\[
\sum_{j=1}^{n_2} a_{ij}^2 = h \sum_{j=1}^{n_1} (\hat{r}_{ij}^{(1)})^2 + \frac{h}{4} \sum_{j=1}^{n_2} \hat{r}_{ij}^2 = O(\frac{1}{N}) , \quad i = 1, \ldots, n
\]

and an analogous argument shows that (4.35) is also valid for \( i = n + 1, \ldots, N \). Therefore condition 1) and 2) in de Jong’s (1987) theorem are satisfied with \( K_N = \log N \). In order to establish the remaining condition 3) in the latter theorem we note that by Gerschgorin’s theorem the eigenvalues \( \mu_1, \ldots, \mu_N \) of the matrix \( A \) can be estimated as follows

\[
m_{\max}^{\max} \mu_i \leq m_{\max} \sum_{l=1}^{N} |a_{il}| \leq \sqrt{h} n_{\max} \sum_{l=1}^{n_1} |\hat{r}_{il}^{(1)}| + \frac{\sqrt{h}}{2} \sum_{l=1}^{n_2} |\hat{r}_{il}| = O(\sqrt{h})
\]
where we used the definition of $\hat{F}_g^{(s)}$ and (4.27), (4.32) in the last estimate. Similarly, we obtain

$$\max_{i=1}^{n_2} |\mu_i| = O(\sqrt{h})$$

which implies $\max_{i=1}^{N} \mu_i^2/\sigma_N^2 = o(1)$. The assertion of Theorem 2.1(i) now follows from de Jong’s (1987) theorem and (4.34), i.e.

$$\sigma_N^{-1} W_N \xrightarrow{p} \mathcal{N}(0,1).$$

### 4.3 Proof of Theorem 2.1: fixed alternatives

If $g_1 \neq g_2$ we have from Lemma 4.0 – 4.4 that

$$\sqrt{N} \left( T_N - M^2 \right) = \sqrt{N} \left( T_N - E[T_N] \right) + o(1) = \sqrt{N} \left( T_N^{(1)} + T_N^{(2)} \right) + o_p(1)$$

$$= \frac{1}{\sqrt{N}} \sum_{i=1}^{N} \sum_{j=1}^{n_i} \alpha_{ij} \varepsilon_{ij} + o_p(1) = W_N + o_p(1)$$

where the last equality defines $W_N$. The assertion now follows from the standard central limit theorem using Ljapunoff’s condition. To this end we note that under a fixed alternative

$$\sigma_N^2 = \text{Var}(W_N) = \gamma^2 + o(1),$$

where we used Lemma 4.1, 4.5 and $\gamma^2 = \gamma_{2,1}^2$ is defined in (2.13) for $k = 2$. For the coefficients $\alpha_{ij}$ in (4.36) we have from (4.30) for the case $i = 1$ and a similar argument in the case $i = 2$

$$\alpha_{ij}^4 = \frac{16^{(\frac{1}{2}r_3 - i)}^4(t_{ij})}{\rho^4(t_{ij})} \sigma_1^4(t_{ij})(g_1 - g_2)^4(t_{ij}) + o(1) \quad (i = 1, 2)$$

which implies Ljapunoff’s condition, i.e.

$$\frac{1}{\sigma_N} \sum_{i=1}^{N} \sum_{j=1}^{n_i} E \left| \frac{\alpha_{ij} \varepsilon_{ij}}{\sqrt{N}} \right|^4 \leq \frac{16n_1}{N^2 \sigma_N} \left( \int_0^{1} \frac{(\frac{1}{2}r_2)^4(t) r_1(t)}{\rho^4(t)} \sigma_1^4(t)(g_1 - g_2)^4(t) \, dt \right)$$

$$+ \int_0^{1} \frac{r_1^4(t)}{\rho(t)} \frac{1/2}{\rho^4(t)} \sigma_2^4(t)(g_1 - g_2)^4(t) \, dt + o(1) = o(1),$$

and completes the proof of Theorem 2.1 (ii).

### 4.4 Some comments on the consistency of the wild bootstrap

In this subsection we briefly indicate the consistency of the wild bootstrap procedure used in the simulation study of Section 3. For the sake of brevity we restrict ourselves to the statistic $T_N^{(1)}$ based on a difference of variance estimators for $k = 2$ samples. Corresponding results for $T_N^{(2)}, T_N^{(3)}$ and $k \geq 3$ regression functions can be proved following a similar pattern. Recall that we again omit all
indices referring to the number of samples and to the specific statistics in our notation (e.g. we use $B$ instead of $B_k^{(1)}$, $T_N$ instead of $T_N^{(1)}$ etc.).

To be precise let $\hat{g}(\cdot, h), \hat{g}_i(\cdot, h)$ denote the estimates of the regression functions from the joint and individual sample defined in (2.4) and (2.6), respectively, where the dependency on the bandwidth $h > 0$ is now stated explicitly. The residuals for the bootstrap sample are given by (see the discussion in Section 3)

$$\hat{\varepsilon}_{ij} = Y_{ij} - \hat{g}(t_{ij}, b), \quad j = 1, \ldots, \eta; \ i = 1,2,$$

$$\varepsilon_{ij}^* = V_{ij}^* \hat{\varepsilon}_{ij},$$

where $b$ is a bandwidth not necessarily equal to the bandwidth $h$ used in the statistic $T_N$ of Section 3.1 and the $V_{ij}^*$ are iid with $E[|V_{ij}^*|^2] = 0$, $E[(V_{ij}^*)^2] = 1$. Throughout this section $E^*$ denotes the conditional expectation given the total sample $\{Y_{ij} \mid j = 1, \ldots, \eta; i = 1,2\}$ and all quantities formed from the bootstrap sample

$$\hat{Y}_{ij}^* = \hat{g}(t_{ij}, b) + \varepsilon_{ij}^*, \quad j = 1, \ldots, \eta; \ i = 1,2,$$

will be denoted with an extra $\star$, e.g. $T_N^\star, \hat{g}^\star$ etc. Under the additional assumption

$$h^{2r+1} = o(b^{2r})$$

we sketch a proof of

$$d_2[N\sqrt{h}(T_N^\star - E^*(T_N^\star)), N(0, \beta^2)] \xrightarrow{P} 0$$

where $B, D$ and $\beta^2 = \beta_{2,1}^2$ are defined in Theorem 2.1 and $d_2[\cdot, \cdot]$ denotes the Mallows distance [see Mallows (1972)]. Applying Lemma 8.8 of Bickel and Freedman (1972) it follows that (4.40) can be established by showing

$$d_2[N\sqrt{h}(T_N^\star - E^*(T_N^\star)), N(0, \beta^2)] \xrightarrow{P} 0$$

$$N\sqrt{h}|E^*(T_N^\star) - Bh^{2r} - \frac{D}{Nh}| \xrightarrow{P} 0$$

$$\beta^2 \xrightarrow{P} \beta^2$$

where

$$\beta^2 = \text{Var}^*(N\sqrt{h}T_N^\star)$$

is the conditional variance of $N\sqrt{h}T_N^\star$.

**Proof of (4.41).** This follows along the lines of the proof of Theorem 2.1 in Section 4.1 - 4.2 and is therefore omitted.

**Proof of (4.43).** Let $T_N^{\star(j)}$ denote the bootstrap versions of the statistics $T_N^{(j)}$ introduced in (4.21) - (4.24) such that

$$T_N^\star - E^*(T_N^\star) = \sum_{j=1}^{7} T_N^{\star(j)}$$

[compare with (4.18),(4.19) and (4.20)]. Conditionally on $\{Y_{ij} \mid j = 1, \ldots, \eta; i = 1,2,\}$ it follows by straightforward algebra

$$\text{Var}^*(T_N^{\star(i)}) = o_p\left(\frac{1}{N^2h}\right), \quad i = 1,2,3,4$$

$$\text{Cov}^*(T_N^{\star(i)}, T_N^{\star(j)}) = o_p\left(\frac{1}{N^2h}\right), \quad i \neq j$$

31
(just repeat the steps in the proofs of Lemma 4.1, 4.2 and 4.5). Moreover

\[
\text{Var}^*(T^{(5)}_{\bar{N}}) = \frac{1}{N^2} \sum_{i \neq t} \frac{(r_{it}^{(1)})^2 + r_{it}^{(1)} r_{ti}^{(1)}}{\sigma_t^2(t, i, t) \sigma_t^2(t, i, t)} \varepsilon_{it}^2 \varepsilon_{ti}^2 + o\left(\frac{1}{N}\right)
\]

where \( r_{it}^{(1)} \) is defined in (4.27) and its asymptotic expansion is derived in the proof of Lemma 4.3. It now follows by a straightforward calculation that the expectation of the left hand side is given by

\[
\frac{2}{N^2 h} \int_0^1 \sigma_1^2(x) \left[1 - \frac{r_1(x)}{\rho(x)}\right]^2 dx \cdot \int (2K - K^2) \theta(u) du + o\left(\frac{1}{N^2 h}\right)
\]

and a tedious calculation for the variance establishes

\[
\text{Var}^*(T^{(5)}_{\bar{N}}) - \text{Var}(T^{(5)}_{\bar{N}}) = o_p\left(\frac{1}{N^2 h}\right).
\]

Similar arguments for \( T^{(6)}_{\bar{N}}, T^{(7)}_{\bar{N}} \) and (4.45), (4.46) establish the assertion (4.43), i.e.

\[
\beta^* - \beta^2 = N^2 h \sum_{j=5}^7 \left\{ \text{Var}^*(T^{(j)}_{\bar{N}}) - \text{Var}(T^{(j)}_{\bar{N}}) \right\} + o_p(1) = o_p(1).
\]

**Proof of (4.42).** Recall the definition of the weights \( w_{ij}^{(\ell)} \), \( \ell = 1, 2 \), \( w_{jk}, i \) in (4.1) and (4.2), respectively. In order to reflect the particular dependency on the bandwidth we denote these quantities with \( w_{ij}^{(\ell)}(h), w_{jk}, i(h) \) etc. A straightforward calculation shows for \( i = 1, 2 \)

\[
E^*[\sigma_{i}^{(2)}] = \frac{1}{n_i} \sum_{j=1}^{n_i} \hat{\delta}_{ij} + \frac{1}{n_i} \sum_{j=1}^{n_i} \hat{\varepsilon}_{ij}^2 + \frac{1}{n_i} \sum_{j=1}^{n_i} \left\{ -2w_{ij}(h) + \sum_{k=1}^{n_i} (w_{jk}(h))^2 \right\} \varepsilon_{ij}^2
\]

and

\[
E^*[\hat{\sigma}^{(2)}] = \frac{1}{N} \sum_{i=1}^{2} \sum_{j=1}^{n_i} \left\{ \hat{\Delta}_{ij}^2 + \hat{\varepsilon}_{ij}^2 \right\} + \frac{1}{N} \sum_{i=1}^{2} \sum_{j=1}^{n_i} \left\{ -2w_{ij}(h) + \sum_{k=1}^{2} w_{ij}(h) \right\} \varepsilon_{ij}^2.
\]

Here \( \hat{\delta}_{ij} \) and \( \hat{\Delta}_{ij} \) denote the analogues of the quantities \( \delta_{ij} \) and \( \Delta_{ij} \) defined in (4.9) and (4.17), respectively, where the regression functions \( \hat{g}(t) \) and \( \hat{g}_j(t) \) have been replaced by the estimate from the combined sample \( \hat{g}(t, b) \). Combining (4.47) and (4.48) yields

\[
E^*[T^*_N] = E^*[\hat{\sigma}^{(2)}] - \frac{n_1}{N} E^*[\sigma_1^{(2)}] - \frac{n_2}{N} E^*[\sigma_2^{(2)}] = \frac{1}{N} \sum_{i=1}^{2} \sum_{j=1}^{n_i} \left( \hat{\Delta}_{ij}^2 - \hat{\delta}_{ij}^2 \right) + \frac{1}{N} \sum_{i=1}^{2} \sum_{j=1}^{n_i} \frac{k_{ij}}{\sigma_t^2(t_{ij})} \varepsilon_{ij}^2
\]

where \( k_{ij} \) is defined in (4.26). Observing that under the null hypothesis of equal curves \( g = g_1 = g_2 \)

\[
\hat{\varepsilon}_{ij} = \sigma_i(t_{ij}) \varepsilon_{ij} + g(t_{ij}) - \hat{g}(t_{ij}, b)
\]

we obtain for the second term in (4.49)

\[
\frac{1}{N} \sum_{i=1}^{2} \sum_{j=1}^{n_i} \frac{k_{ij}}{\sigma_t^2(t_{ij})} \varepsilon_{ij}^2 - \frac{1}{N h} D = \frac{1}{N} \sum_{i=1}^{2} \sum_{j=1}^{n_i} k_{ij} \varepsilon_{ij} - \frac{1}{N h} D + o_p\left(\frac{1}{N \sqrt{h}}\right)
\]

\[
= \frac{1}{N} \sum_{i=1}^{2} \sum_{j=1}^{n_i} k_{ij} E[\varepsilon_{ij}^2] - \frac{1}{N h} D + o_p\left(\frac{1}{N \sqrt{h}}\right) = o_p\left(\frac{1}{N \sqrt{h}}\right)
\]

32
where the first equality follows from the uniform consistency of the estimate \( \hat{g}(\cdot, b) \) [see e.g., Mack and Silverman (1982)], the second equality from (4.31) in the proof of Lemma 4.2 and the third equality is obtained by a similar argument as given in the proof of Lemma 4.0 observing the definition of \( k_{ij} \), (4.31) and \( E[\varepsilon_i^2] = 1 \). For the first term in (4.49) it can be proved by similar arguments

\[
\frac{1}{N} \sum_{i=1}^{n_i} \sum_{j=1}^{n_j} (\hat{\Delta}_{ij}^2 - \hat{\delta}_{ij}^2) - B N^{2\varepsilon} = o_p\left( \frac{1}{N \sqrt{h}} \right)
\]

and a combination of (4.49), (4.50) and (4.51) yields (4.42), which completes the proof of assertion (4.40).
