Abstract

In this paper, we consider the problem of determining the optimal block size for a spatial subsampling method for spatial processes observed on regular grids. We derive expansions for the mean square error of the subsampling variance estimator, which yields an expression for the theoretical optimal block size. The theoretical optimal block size is shown to depend in an intricate way on the geometry of the spatial sampling region as well as on the characteristics of the underlying random field. Final expressions for the optimal block size make use of some nontrivial estimates of lattice point counts in shifts of convex sets. Examples are presented to illustrate the variations in optimal block size for sampling regions of different shapes.

Key Words: Block bootstrap, block size, lattice point count, mixing, nonparametric variance estimation, random fields, spatial statistics, subsampling method

1 Introduction

We examine the problem of choosing subsample sizes to maximize the performance of subsampling methods for variance estimation. The data at hand are viewed as realizations of a stationary, weakly dependent, spatial lattice process. We consider the common scenario of sampling from sites of regular distance (e.g., indexed by the integer lattice $\mathbb{Z}^d$), lying within some region $R_n$, embedded in $\mathbb{R}^d$. Such lattice data appear often in time series, agricultural field trials, and remote sensing and image analysis (medical and satellite image processing).

For variance estimation via subsampling, the basic idea is to construct several “scaled-down” copies of the sampling region $R_n$ (subsamples) that fit inside $R_n$, evaluate the analog of $\hat{\theta}_n$ on each of these subregions, and then compute a properly normalized sample variance from the resulting values. The $R_n$-sampling scheme is essentially recreated at the level of the subregions. Two subsampling designs are most typical: subregions can be maximally overlapping (OL) or devised to be non-overlapping (NOL). The accuracy (e.g., variance and bias) of subsample-based estimators depends crucially on the choice of subsample size.

To place our work into perspective, we briefly outline previous research in variance estimation with subsamples and theoretical size considerations. The concept of variance estimation
through subsampling originated from analysis of weakly dependent time processes. Let \( \hat{\theta}_n \) be an estimator of a parameter of interest \( \theta \) based on \( \{ Z(1), \ldots, Z(n) \} \) from a stationary temporal process \( \{ Z(t) \}_{t \geq 1} \). To obtain subsamples from a stationary stretch \( Z(1), \ldots, Z(n) \) in time, Carlstein (1986) first proposed the use of NOL blocks of length \( m \leq n \):

\[
\left\{ Z(1+(i-1)m), \ldots, Z(im) \right\}, \quad \text{for } i = 1, \ldots, \lfloor n/m \rfloor,
\]

while the sequence of subsseries:

\[
\left\{ Z(i), \ldots, Z(i+m-1) \right\} \quad \text{for } i = 1, \ldots, n - m + 1
\]

provides OL subsamples of length \( m \) (cf. Künsch, 1989; Politis and Romano, 1993b). Here, \( \lfloor x \rfloor \) denotes the integer part of a real number \( x \). In each respective collection, evaluations of an analog statistic \( \hat{\theta}_i \) are made for each subseries and a normalized sample variance is calculated to estimate the parameter \( n \text{Var}(\hat{\theta}_n) \):

\[
S_n^2 = \sum_{i=1}^{J} \frac{m(\hat{\theta}_i - \hat{\theta})^2}{J}, \quad \hat{\theta} = \sum_{i=1}^{J} \frac{\hat{\theta}_i}{J},
\]

where \( J = \lfloor n/m \rfloor \) (\( J = n - m + 1 \)) for the NOL (OL) subsample-based estimator. Carlstein (1986) and Fukuchi (1999) established the \( L_2 \) consistency of the NOL and OL estimators, respectively, for the variance of a general (not necessarily linear) statistic. Politis and Romano (1993b) determined asymptotic orders of the variance \( O(m/n) \) and bias \( O(1/m) \) of the subsample variance estimators for linear statistics. For mixing time series, they found that a subsample size \( m \) proportional to \( n^{1/3} \) is optimal in the sense of minimizing the Mean Square Error (MSE) of variance estimation, concuring also with optimal block order for the moving block bootstrap variance estimator [Hall et al. (1995), Lahiri (1996)].

Cressie (1991, p. 492) conjectured the recipe for extending Carlstein’s variance estimator to the general spatial setting, obtaining subsamples by tilting the sample region \( R_n \) with disjoint “congruent” subregions. Politis and Romano (1993a, 1994) have shown the consistency of subsample-based variance estimators for rectangular sampling/subsampling regions in \( \mathbb{R}^d \) when the sampling sites are observed on \( Z^d \cap \prod_{i=1}^{d} [1, n_i] \) and integer translates of \( \prod_{i=1}^{d} [1, m_i] \) yield the subsamples. Garcia-Soidan and Hall (1997) and Posso1 (1991) proposed similar estimators under an identical sampling scenario. For linear statistics, Politis and Romano (1993a) determined that a subsampling scaling choice \( \prod_{i=1}^{d} m_i = C(\prod_{i=1}^{d} n_i)^{d/(d+2)} \), for some unknown \( C \), minimizes the order of a variance estimator’s asymptotic MSE. Sherman and Carlstein (1994) and Sherman (1996) proved the MSE-consistency of NOL and OL subsample estimators, respectively, for the variance of general statistics in \( \mathbb{R}^2 \). Their work allowed for a more flexible sampling scheme: the “inside” of a simple closed curve defines a set \( D \subset [-1, 1]^2 \), \( Z^2 \cap nD \) (using a scaled-up copy of \( D \) constitutes the set of sampling sites, and translates of \( nD \) within \( nD \) form subsamples. Sherman (1996) minimized a bound on the asymptotic order of the OL estimator’s MSE to argue that the best size choice for OL subsamples involves \( m = O(n^{1/2}) \) (coinciding with the above findings of Politis and Romano (1993a) for rectangular regions in \( \mathbb{R}^2 \)). Politis and Sherman (2001) have developed consistent subsampling methods for variance estimation with marked point process data [cf. Politis et al. (1999), Chapter 6].

Few theoretical and numerical recommendations for choosing subsamples have been offered
in the spatial setting, especially with the intent of variance estimation. As suggested in the literature, an explicit theoretical determination of optimal subsample "scaling" (size) requires calculation of an order and associated proportionality constant for a given sampling region $R_n$. Even for the few sampling situations where the order of optimal subsample size has been established, the exact adjustments to these orders are unknown and, quoting Politis and Romano (1993a), "important (and difficult) in practice." Beyond the time series case with the univariate sample mean, the influence of the geometry and dimension of $R_n$, as well as the structure of $\hat{\theta}_n$, on precise subsample selection has not been explored. We attempt here to advance some ideas on the best size choice, both theoretically and empirically, for subsamples.

We work under the "smooth function" model of Hall (1992), where the statistic of interest $\hat{\theta}_n$ can be represented as a function of sample means. We formulate a framework for sampling in $\mathbb{R}^d$ where the sampling region $R_n$ (say) is obtained by "inflating" a prototype set in the unit cube in $\mathbb{R}^d$ and the subsampling regions are given by suitable translates of a scaled down copy of the sampling region $R_n$. We consider both a non-overlapping version and a (maximal) overlapping version of the subsampling method. For each method, we derive expansions for the variance and the bias of the corresponding subsample estimator of $\text{Var}(\hat{\theta}_n)$. The asymptotic variance of the spatial subsample estimator for the OL version turns out to be smaller than that of the NOL version by a constant factor $K_1$ (say) which depends solely on the geometry of the sampling region $R_n$. In the time series case, Meketon and Schmeiser (1984), Künsch (1989), Hall et al. (1995) and Lahiri (1996) have shown in different degrees of generality that the asymptotic variance under the OL subsampling scheme, compared to the NOL one, is $K_1 = \frac{2}{3}$ times smaller. Results of this paper show that for rectangular sampling regions $R_n$ in $d$-dimensional space, the factor $K_1$ is given by $(\frac{2}{3})^d$. We list the factor $K_1$ for sampling regions of some common shapes in Table 1.

<table>
<thead>
<tr>
<th>Shape of $R_n$</th>
<th>Rectangle in $\mathbb{R}^d$</th>
<th>Sphere in $\mathbb{R}^3$</th>
<th>Circle in $\mathbb{R}^2$</th>
<th>Right triangle in $\mathbb{R}^2$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$K_1$</td>
<td>$(\frac{2}{3})^d$</td>
<td>$17\pi/315$</td>
<td>$\pi/4 - 4/(3\pi)$</td>
<td>$1/5$</td>
</tr>
</tbody>
</table>

In contrast, the bias parts of both the OL and NOL subsample variance estimators are (usually) asymptotically equivalent and depend on the covariance structure of the random field as well as on the geometry of the sampling region $R_n$. Since the bias term is typically of the same order as the number of lattice points lying near a subsample's boundary, determination of the leading bias term involves some nontrivial estimates of the lattice point counts over translated subregions. Counting lattice points in scaled-up sets is a hard problem and has received a lot of attention in Analytic Number Theory and in Combinatorics. Even for the case of the plane (i.e., $d = 2$), the counting results available in the literature are directly applicable to our problem only for a very restricted class of subregions (that have the so-called "smoothly winding border" [cf. van der Corput (1920), Huxley (1993, 1996)]). Here explicit expressions for the bias terms are derived for a more general class of sampling regions using some new estimates on the discrepancy between the number of lattice points and the volume of the shifted subregions in the plane and in three dimensional Euclidean space. In particular, our results are applicable to sampling regions that do not necessarily have "smoothly winding borders".

Minimizing the combined expansions for the bias and the variance parts, we derive explicit expressions for the theoretical optimal block size for sampling regions of different shapes. To
briefly describe the result for a few common shapes, suppose the sampling region \( R_n \) is obtained by inflating a given set \( R_0 \in (-\frac{1}{2}, \frac{1}{2})^d \) by a scaling constant \( \lambda_n \) as \( R_n = \lambda_n R_0 \) and that the subsamples are formed by considering the translates of \( \lambda R_n = \lambda \lambda_n R_0 \). Then, the theoretically optimal choice of the block size \( \lambda_n \) for the OL version is of the form

\[
\lambda_n^{\text{opt}} = \left( \frac{\lambda^d D_0^2}{d \lambda_n^t} \right)^{1/(d+2)} (1 + o(1)) \quad \text{as} \quad n \to \infty
\]

for some constants \( B_0 \) and \( K_0 \) (coming from the bias and the variance terms, respectively), where \( \tau^2 \) is a population parameter that does not depend on the shape of the sampling region \( R_n \) (see Theorem 5.1 for details). The following table lists the constants \( B_0 \) and \( K_0 \) for some shapes of \( R_n \). It follows from Table 2 that, unlike the time series case, in higher dimensions the optimal block size critically depends on the shape of the spatial sampling region \( R_n \). It simplifies only slightly for the NOL subsampling scheme as the constant \( K_0 \) is unnecessary for computing optimal NOL subsamples, but the bias constant \( B_0 \) is often the same for both estimators from each version of subsampling. These expressions may be readily used to obtain 'plug-in' estimates of the theoretical optimal block lengths for use in practice.

The rest of the paper is organized as follows. In Section 2, we describe the spatial subsampling method and state the Assumptions used in the paper. In Sections 3 and 4, we respectively derive expansions for the variance and the bias parts of the subsampling estimators. Theoretical optimal block lengths are derived in Section 5. The results are illustrated with some common examples in Section 6. Section 7 addresses data-based subsample size selection. Proofs of variance and bias results are separated into Sections 8 and 9, respectively.

### 2 Variance estimators via subsampling

In Section 2.1, we frame the sampling design and the structure of the sampling region. Two methods of subsampling are presented in Section 2.2 along with corresponding nonparametric variance estimators. Assumptions and Conditions used in the paper are given in Section 2.3.
2.1 The sampling structure

To describe the sampling scheme used, we first assume all potential sampling sites are located on a translate of the rectangular integer lattice in \( \mathbb{R}^d \). For a fixed (chosen) vector \( \mathbf{t} \in [-1/2, 1/2]^d \), we identify the \( \mathbf{t} \)-translated integer lattice as \( \mathbb{Z}^d \equiv \mathbf{t} + \mathbb{Z}^d \). Let \( \{Z(s) : s \in \mathbb{Z}^d \} \) be a stationary weakly dependent random field (hereafter r.f.) taking values in \( \mathbb{R}^p \). (We use bold font as a standard to denote vectors in the space of sampling \( \mathbb{R}^d \) and normal font for vectors in \( \mathbb{R}^p \), including \( Z(\cdot) \).) We suppose that the process \( Z(\cdot) \) is observed at sampling sites lying within the sampling region \( R_n \subset \mathbb{R}^d \). Namely, the collection of available sampling sites is

\[
\{Z(s) : s \in R_n \cap \mathbb{Z}^d \}.
\]

To obtain the results in the paper, we assume that the sampling region \( R_n \) becomes unbounded as the sample size increases. This will provide a commonly used “increasing domain” framework for studying asymptotics with spatial lattice data [cf. Cressie (1991)]. We next specify the structure of the regions \( R_n \) and employ a formulation similar to that of Lahiri (1999a,b).

Let \( R_0 \) be a Borel subset of \( (-1/2, 1/2)^d \) containing an open neighborhood of the origin such that for any sequence of positive real numbers \( a_n \to 0 \), the number of cubes of the scaled lattice \( a_n \mathbb{Z}^d \) which intersect the closures \( \overline{R_0} \) and \( \overline{R_0} \) is \( O((a_n^{-1})^{d-1}) \) as \( n \to \infty \). Let \( \Delta_n \) be a sequence of \( d \times d \) diagonal matrices, with positive diagonal elements \( \lambda_1^{(n)}, \ldots, \lambda_d^{(n)} \), such that each \( \lambda_j^{(n)} \to \infty \) as \( n \to \infty \). We assume that the sampling region \( R_n \) is obtained by “inflating” the template set \( R_0 \) by the directional scaling factors \( \Delta_n \); that is,

\[
R_n = \Delta_n R_0.
\]

Because the origin is assumed to lie in \( R_0 \), the sampling region \( R_n \) grows outward in all directions as \( n \) increases. Furthermore, if the scaling factors are all equal \( (\lambda_1^{(n)} = \cdots = \lambda_d^{(n)}) \), the shape of \( R_n \) remains the same for different values of \( n \).

The formulation given above allows the sampling region \( R_n \) to have a large variety of fairly irregular shapes with the boundary condition on \( R_0 \) imposed to avoid pathological cases. Some common examples of such regions are convex subsets of \( \mathbb{R}^d \), such as spheres, ellipsoids, polyhedrons, as well as certain non-convex subsets with irregular boundaries, such as star-shaped regions. Sherman and Carlstein (1994) and Sherman (1996) consider a similar class of such regions in the plane (i.e. \( d = 2 \)) where the boundaries of the sets \( R_0 \) are delineated by simple rectifiable curves with finite lengths. The border requirements on \( R_0 \) ensure that the number of observations near the boundary of \( R_n \) is negligible compared to the totality of data values. This assumption is crucial to the derivation of results to follow. In addition, Perera (1997) demonstrates that the border geometry of \( R_0 \) can significantly influence the asymptotic distribution of sample means taken with observations from “expanding” sets, like \( R_n \).

2.2 Subsampling designs and variance estimators

We suppose that the relevant statistic, whose variance we wish to estimate, can be represented as a function of sample means. Let \( \hat{\theta}_n = H(\bar{Z}_{N_n}) \) be an estimator of the population parameter of interest \( \theta = H(\mu) \), where \( H : \mathbb{R}^p \to \mathbb{R} \) is a smooth function, \( E[Z(\cdot)] = \mu \in \mathbb{R}^p \) is the mean of the stationary r.f. \( Z(\cdot) \), and \( \bar{Z}_{N_n} \) is the sample mean of the \( N_n \) observations within \( R_n \). We can write

\[
\bar{Z}_{N_n} = N_n^{-1} \sum_{s \in \mathbb{Z}^d \cap R_n} Z(s). \tag{21}
\]
This parameter and estimator formulation is what Hall (1992) calls the “smooth function” model and it has been used in other scenarios, such as with the moving block bootstrap (MBB) and empirical likelihood, for studying approximately linear functions of a sample mean [Lahiri (1996), DiCiccio et al. (1991)]. By considering suitable functions of the Z(s)'s, one can represent a wide range of estimators under the present framework. In particular, these include means, products and ratios of means, autocorrelation estimators, sample lag cross-correlation estimators [Politis and Romano (1993b)], and Yule-Walker estimates for autoregressive processes [cf. Guyon (1995)].

The quantity which we seek to estimate nonparametrically is the variance of the normalized statistic $\sqrt{N_n} \bar{Y}_n$, say, $\tau^2_n = N_n E(\bar{Y}_n - E\bar{Y}_n)^2$. In our problem, this goal is equivalent to consistently estimating the limiting variance $\tau^2 = \lim_{n \to \infty} \tau^2_n$.

2.2.1 Overlapping subsamples

Variance estimation with OL subsampling regions has been presented previously in the literature, though in more narrow sampling situations. Sherman (1996) considered an OL subsample-based estimator for sampling regions in $\mathbb{R}^2$; Politis and Romano (1994) extended a similar estimator for rectangular regions in $\mathbb{R}^d$ with faces parallel to the coordinate axes (i.e. $R_0 = (-1/2, 1/2]^d$); and a host of authors, in a variety of contexts, have examined OL subsample estimators applied to time series data [cf. Song and Schmeiser (1988), Politis and Romano (1993a), Fukuchi (1999)].

We first consider creating a smaller version of $R_n$, which will serve as a template for the OL subsampling regions. To this end, let $\Delta_n$ be a $d \times d$ diagonal matrix with positive diagonal elements, $\{\lambda_1^{(n)}, \ldots, \lambda_d^{(n)}\}$, such that $\lambda_i^{(n)}/\lambda_i \to 0$ and $\lambda_i^{(n)} \to \infty$, as $n \to \infty$, for each $i = 1, \ldots, d$. (The matrix $\Delta_n$ represents the determining scaling factors for $R_n$ and $\Delta_n$ shall be factors used to define the subsamples.) We make the “prototype” subsampling region,

$$\mathcal{R}_n = \mathcal{R}_n R_0,$$

and identify a subset of $\mathbb{Z}^d$, say $J_{OL}$, corresponding to all integer translates of $\mathcal{R}_n$ lying within $R_n$. That is,

$$J_{OL} = \left\{ i \in \mathbb{Z}^d : i + \Delta \mathcal{R}_n \subset R_n \right\}.$$

The desired OL subsampling regions are precisely the translates of $\mathcal{R}_n$ given by: $R_{i,n} = i + \Delta \mathcal{R}_n$, $i \in J_{OL}$. Note that the origin belongs to $J_{OL}$ and, clearly, some of these subregions overlap.

Let $s N_n = |\mathbb{Z}^d \cap R_n|$ be the number of sampling sites in $\mathcal{R}_n$ and let $|J_{OL}|$ denote the number of available subsampling regions. (The number of sampling sites within each OL subsampling region is the same, namely for any $i \in J_{OL}$, $s N_n = |\mathbb{Z}^d \cap R_{i,n}|$.) For each $i \in J_{OL}$, compute $\hat{\theta}_i = H(Z_{i,n})$, where

$$Z_{i,n} = s N_n^{-1} \sum_{s \in \mathbb{Z}^d \cap R_{i,n}} Z(s)$$

denotes the sample mean of observations within the subregion. We then have the OL subsample variance estimator of $\tau^2_n$ as

$$\hat{\tau}^2_{n,\text{OL}} = |J_{OL}|^{-1} \sum_{i \in J_{OL}} s N_n \left( \hat{\theta}_{i,n} - \hat{\theta}_n \right)^2, \quad \hat{\theta}_n = |J_{OL}|^{-1} \sum_{i \in J_{OL}} \hat{\theta}_{i,n}.$$
2.2.2 Non-overlapping subsamples

Carlstein (1986) first proposed a variance estimator involving NOL subsamples for time processes. Politis and Romano (1993a) and Sherman and Carlstein (1994) demonstrated the consistency of variance estimation, via NOL subsampling, for certain rectangular regions in \(\mathbb{R}^d\) and some sampling regions in \(\mathbb{R}^2\), respectively. Here we adopt a formulation similar to those of Sherman and Carlstein (1994) and Lahiri (1999a).

The sampling region \(R_n\) is first divided into disjoint “cubes”. Let \(s\Delta_n\) be the previously described \(d \times d\) diagonal matrix from (2.2), which will determine the “window width” of the partitioning cubes. Let

\[
J_{NOL} = \left\{ i \in \mathbb{Z}^d : s\Delta_n \left( i + (-1/2, 1/2)^d \right) \subseteq R_n \right\}
\]

represent the set of all “inflated” subcubes that lie inside \(R_n\). Denote its cardinality as \(|J_{NOL}|\). For each \(i \in J_{NOL}\), define the subsampling region \(\tilde{R}_{i,n} = s\Delta_n(i + R_0)\) by inscribing the translate of \(s\Delta_n R_0\) such that the origin is mapped onto the midpoint of the cube \(s\Delta_n(i + (-1/2, 1/2)^d)\). This provides a collection of NOL subsampling regions, which are smaller versions of the original sampling region \(R_n\), that lie inside \(R_n\).

For each \(i \in J_{NOL}\), the function \(H(\cdot)\) is evaluated at the sample mean, say \(\bar{Z}_{i,n}\) for a corresponding subsampling region \(\tilde{R}_{i,n}\) to obtain \(\tilde{\theta}_{i,n} = H(\bar{Z}_{i,n})\). The NOL subsample estimator of \(\tau_n^2\) is again an appropriately scaled sample variance:

\[
\tau_{n,NOL}^2 = \frac{1}{|J_{NOL}|} \sum_{i \in J_{NOL}} sN_{i,n} \left( \tilde{\theta}_{i,n} - \tilde{\theta}_n \right)^2, \quad \tilde{\theta}_n = \frac{1}{|J_{NOL}|} \sum_{i \in J_{NOL}} \tilde{\theta}_{i,n}
\]

where \(sN_{i,n} = |\mathbb{Z}^d \cap \tilde{R}_{i,n}|\) denotes the number of sampling sites within a given NOL subsample.

We note that \(sN_{i,n}\) may differ between NOL subsamples, but all such subsamples will have exactly \(sN_{i,n} = sN_n\) sites available if the diagonal elements of \(s\Delta_n\) are integers.

2.3 Assumptions

For stating the assumptions, we need to introduce some notation. For a vector \(x = (x_1, \ldots, x_d)^T \in \mathbb{R}^d\), let \(\|x\|\) and \(\|x\|_1 = \sum_{i=1}^d |x_i|\) denote the usual Euclidean and \(l^1\) norms of \(x\), respectively. Denote the \(l^\infty\) norm as \(\|x\|_\infty = \max_{1 \leq k \leq d} |x_k|\). Define \(dist(E_1, E_2) = \inf \{ \|x - y\| : x \in E_1, y \in E_2 \}\) for two sets \(E_1, E_2 \subseteq \mathbb{R}^d\). We shall use the notation \(|\cdot|\) also in two other cases: for a countable set \(B\), \(|B|\) would denote the cardinality of the set \(B\); for an uncountable set \(A \subseteq \mathbb{R}^d\), \(|A|\) would refer to the volume (i.e., the \(\mathbb{R}^d\) Lebesgue measure) of \(A\).

Let \(\mathcal{F}_Z(T) = \sigma(Z(s) : s \in T)\) be the \(\sigma\)-field generated by the variables \(\{Z(s) : s \in T\}\), \(T \subseteq \mathbb{Z}^d\). For \(T_1, T_2 \subseteq \mathbb{Z}^d\), write

\[
\alpha(T_1, T_2) = \sup \{|P(A \cap B) - P(A)P(B)| : A \in \mathcal{F}_Z(T_1), B \in \mathcal{F}_Z(T_2)\}.
\]

Then, the strong mixing coefficient for the r.f. \(Z(\cdot)\) is defined as

\[
\alpha(k, l) = \sup \{\alpha(T_1, T_2) : T_i \subseteq \mathbb{Z}^d, |T_i| \leq l, i = 1, 2; \ dist(T_1, T_2) \geq k\} \quad (2.3)
\]

Note that the supremum in the definition of \(\alpha(k, l)\) is taken over sets \(T_1, T_2\) which are bounded. For \(d > 1\), this is important. A r.f. on the (rectangular) lattice \(\mathbb{Z}^d\) with \(d \geq 2\) that satisfies a strong mixing condition of the form

\[
\lim_{k \to \infty} \sup \{\alpha(T_1, T_2) : T_1, T_2 \subseteq \mathbb{Z}^d, \ dist(T_1, T_2) \geq k\} = 0 \quad (2.4)
\]
with supremum taken over possibly unbounded sets necessarily belongs to the more restricted class of \( \rho \)-mixing r.f.’s [cf. Bradley (1989)]. Politis and Romano (1993a) used moment inequalities based on the mixing condition in (2.4) to determine the orders of the bias and variance of \( \hat{\tau}^2, \hat{\tau}^2_{n,\text{OL}} \) for rectangular sampling regions.

For proving the subsequent theorems, the assumptions below are needed along with two conditions stated as functions of a positive argument \( r \in \mathbb{Z}_+ = \{0, 1, 2, \ldots \} \). In the following, \( \det(\Delta) \) represents the determinant of a square matrix \( \Delta \). For \( \alpha = (\alpha_1, \ldots, \alpha_n)' \in (\mathbb{Z}_+)^p \), let \( D^n \) denote the \( n \)th order partial differential operator \( \partial^{\alpha_1+\cdots+\alpha_n}/\partial x_1^{\alpha_1} \cdots \partial x_p^{\alpha_p} \) and \( \nabla = (\partial H(\mu)/\partial x_1, \ldots, \partial H(\mu)/\partial x_p)' \) be the vector of first order partial derivatives of \( H \) at \( \mu \).

Limits in order symbols are taken letting \( n \) tend to infinity.

**Assumptions:**

(A.1) There exists a \( d \times d \) diagonal matrix \( \Delta_0 \), \( \det(\Delta_0) > 0 \), such that

\[
\frac{1}{s\lambda^{(n)}_i}, \Delta_n \to \Delta_0.
\]

(A.2) For the scaling factors of the sampling and subsampling regions:

\[
\sum_{i=1}^d \frac{1}{s\lambda^{(n)}_i} + \sum_{i=1}^d \frac{s\lambda^{(n)}_i}{\lambda_i^{(n)}} + \frac{[\det(\Delta_n)]^{(d+1)/d}}{\det(\Delta_n)} = o(1), \quad \max_{1 \leq i \leq d} \lambda^{(n)}_i = O\left(\min_{1 \leq i \leq d} \lambda^{(n)}_i\right).
\]

(A.3) There exist nonnegative functions \( \alpha_1(\cdot) \) and \( g(\cdot) \) such that \( \lim_{k \to \infty} \alpha_1(k) = 0 \), \( \lim_{l \to \infty} g(l) = \infty \) and the strong-mixing coefficient \( \alpha(k, l) \) from (2.3) satisfies the inequality

\[
\alpha(k, l) \leq \alpha_1(k)g(l) \quad k > 0, \; l > 0.
\]

(A.4) \( \sup\{\hat{\alpha}(T_1, T_2) : T_1, T_2 \subset \mathbb{Z}^d, |T_1| = 1, \; \text{dis}(T_1, T_2) \geq k\} = o(k^{-d}). \)

(A.5) \( \tau^2 > 0 \), where \( \tau^2 = \sum_{k \in \mathbb{Z}^d} \sigma(k), \; \sigma(k) = \text{Cov}(\nabla'Z(t), \nabla'Z(t+k)) \).

**Conditions:**

\( D_r : \; H : \mathbb{R}^p \to \mathbb{R} \) is \( r \)-times continuously differentiable and, for some \( a \in \mathbb{Z}_+ \) and real \( C > 0 \),

\[
\max\{|D^rH(\mathbf{x})| : \|\mathbf{x}\| = r\} \leq C(1 + \|\mathbf{x}\|^a), \quad \mathbf{x} \in \mathbb{R}^p.
\]

\( M_r : \) For some \( 0 < \delta \leq 1, \; 0 < \kappa < (2r - 1 - 1/d)(2r + \delta)/\delta, \) and \( C > 0 \),

\[
E\|Z(t)\|^{2r+\delta} < \infty, \quad \sum_{x=1}^{\infty} x^{(2r-1)d-1} \alpha_1(x)^{\delta/(2r+\delta)} < \infty, \quad g(x) \leq Cx^{\delta}.
\]

Some comments about the assumptions and the conditions are in order.

Assumption A.5 implies a positive, finite asymptotic variance \( \tau^2 \) for the standardized estimator, \( \sqrt{\hat{\tau}^2_n} \). We would like \( \tau^2 \in (0, \infty) \) for a purposeful variance estimation procedure.

In Assumption A.3, we formulate a conventional bound on the mixing coefficient \( \alpha(k, l) \) from (2.3) that is applicable to many r.f.s and resembles the mixing assumption of Lahiri (1999a, b).
For r.f.s satisfying Assumption A.3, the “distance” component of the bound, $\alpha_1(\cdot)$, often decreases at an exponential rate while the function of “set size,” $g(\cdot)$, increases at a polynomial rate [cf. Guyon (1995)]. Examples of r.f.s that meet the requirements of A.3 and $M_r$ include Gaussian fields with analytic spectral densities, certain linear fields with a moving average or autoregressive (AR) representation (like $m$-dependent fields), separable AR(1) x AR(1) lattice processes suggested by Martin (1990) for modeling in $\mathbb{R}^2$, many Gibbs and Markov fields, and important time series models [cf. Doukhan (1994)]. Condition $M_r$ combined with A.3 also provides useful moment bounds for normed sums of observations (see Lemma 8.2).

Assumption A.4 permits the CLT in Bollhansen (1982) to be applied to sums of $Z(\cdot)$ on sets of increasing domain, in conjunction with the boundary condition on $R_0$, Assumption A.3, and Condition $M_r$. This version of the CLT (Stein’s method) is derived from $\alpha$-mixing conditions which ensure asymptotic independence between a single point and observations in arbitrary sets of increasing distance [cf. Perera (1997)].

Assumptions A.1 and A.2 set additional guidelines for how sampling and subsampling design parameters, $\Delta_n$ and $\lambda_n$, may be chosen. The assumptions provide a flexible framework for handling “increasing domains” of many shapes. For $d = 1$, A.1-A.2 are equivalent to the requirements of Lahiri (1999c) who provides variance and bias expansions for the MBB variance estimator with weakly dependent time processes.

3 Variance expansions

We now give expansions for the asymptotic variance of the OL/NOL subsample variance estimators $\hat{\tau}^2_{n,OL}$ and $\hat{\tau}^2_{n,NOL}$ of $\tau^2_n = N_n \text{Var}(\hat{\theta}_n)$.

**Theorem 3.1** Suppose that Assumptions A.1 - A.5 and Conditions D2 and $M_{\lambda+n}$ hold, then

\[ (a) \quad \text{Var}(\hat{\tau}^2_{n,OL}) = K_0 \cdot \frac{\det(\lambda_n)}{\det(\Delta_n)} \cdot [2\pi n^3] (1 + o(1)), \]

\[ (b) \quad \text{Var}(\hat{\tau}^2_{n,NOL}) = \frac{1}{|R_0|^d} \cdot \frac{\det(\lambda_n)}{\det(\Delta_n)} \cdot [2\pi n^3] (1 + o(1)), \]

where $K_0 = \frac{1}{|R_0|^d} \int_{\mathbb{R}^d} \frac{|(x + R_0) \cap R_0|^2}{|R_0|^2} \, dx$ is an integral with respect to the $\mathbb{R}^d$ Lebesgue measure.

The constant $K_0$ appearing in the variance expansion of the estimator $\hat{\tau}^2_{n,OL}$ is a property of the shape of the sampling template $R_0$ but not of its exact embedding in space $\mathbb{R}^d$ or even the scale of the set. Namely, $K_0$ is invariant to invertible affine transformations applied to $R_0$ and hence can be computed from either $R_0$ or $R_n = \Delta_n R_0$. Values of $K_0$ for some template shapes are given in Table 3 and Section 6.

A stationary time sequence $Z_1, \ldots, Z_n$ can be obtained within our sampling formulation by choosing $R_0 = (-1/2, 1/2)$ and $\lambda^{(n)} = n$ on the untranslated integer lattice $Z = Z$. In this special sampling case, an application of Theorem 3.1 yields

\[ \text{Var}(\hat{\tau}^2_{n,OL}) = 2/3 \cdot \text{Var}(\hat{\tau}^2_{n,NOL}), \quad \text{Var}(\hat{\tau}^2_{n,NOL}) = \lambda^{(n)} / \lambda^{(n)} : [2\pi n^3] (1 + o(1)), \]

a result which is well-known for “nearly” linear functions $\hat{\theta}_n$ of a time series sample mean [cf. Künsch (1989)]. Theorem 3.1 implies that, under the “smooth” function model, the asymptotic
Table 3: Examples of $K_0$ from Theorem 3.1 for several shapes of $R_0 \subset \mathbb{R}^d$. *The trapezoid has a $90^\circ$ interior $\angle$ and parallel sides $b_2 \geq b_1; c = (b_2/b_1 + 1)^{-2}[1 + 2(b_2/b_1 - 1)/(b_2/b_1 + 1)]$.

The variance of the OL subsample-based variance estimator is always strictly less than the NOL version because

$$K_1 = \lim_{n \to \infty} \frac{\text{Var}(\hat{\tau}_{n,OL}^2)}{\text{Var}(\hat{\tau}_{n,NOL}^2)} = K_0 |R_0| < 1. \tag{3.1}$$

If both estimators have the same bias (which is often the case), (3.1) implies that variance estimation with OL subsamples is more efficient than the NOL subsample alternative owing to a smaller asymptotic MSE.

Unlike $K_0$, $K_1$ does depend on the volume $|R_0|$, which in turn is constrained by the $R_0$-template’s geometry. That is, $K_1$ is ultimately bounded, through $|R_0|$ in (3.1), by the amount of space that an object of $R_0$’s shape can possibly occupy within $(-1/2,1/2)^d$, or by how much volume can be filled by a given geometrical body (e.g. circle) compared to a cube. The constants $K_1$ in Table 1 are computed with templates of prescribed shape and largest possible volume in $(-1/2,1/2)^d$. These values most accurately reflect the influence of $R_0$’s (or $R_n$’s) geometry on the relative performance (i.e. variance, efficiency) of the estimators $\hat{\tau}_{n,OL}^2$ and $\hat{\tau}_{n,NOL}^2$.

To conclude this section, we remark that both subsample-based variance estimators can be shown to be (MSE) consistent under Theorem 3.1 conditions, allowing for more general spatial sampling regions, in both shape and dimension, than previously considered. Inference on the parameter $\theta$ can be made through the limiting standard normal distribution of $\sqrt{N_n}(\hat{\theta}_n - \theta)/\hat{\tau}_n$ for $\hat{\tau}_n = \hat{\tau}_{n,OL}$ or $\hat{\tau}_{n,NOL}$.

4 Bias expansions

We now try to capture and precisely describe the leading order terms in the asymptotic bias of each subsample-based variance estimator, similar to the variance determinations from the previous section. We first establish and note the order of the dominant component in the bias expansions of $\hat{\tau}_{n,OL}^2$ and $\hat{\tau}_{n,NOL}^2$, which is the subject of the following lemma.

**Lemma 4.1** With Assumptions A.1 - A.5, suppose that Conditions D$_2$ and M$_{2+a}$ hold for $d \geq 2$; and D$_3$ and M$_{3+a}$ for $d = 1$. Then, the subsample estimators of $\tau_n^2 = N_n \text{Var}(\hat{\theta}_n)$ have expectations:

$$\text{E}(\hat{\tau}_{n,OL}^2) = \tau_n^2 + O(1/\lambda_1^{(n)}) \quad \text{and} \quad \text{E}(\hat{\tau}_{n,NOL}^2) = \tau_n^2 + O(1/\lambda_1^{(n)}).$$

The lemma shows that, under the smooth function model, the asymptotic bias of each estimator is $O(1/\lambda_1^{(n)})$ for all dimensions of sampling. Politis and Romano (1993a, p.323) and Sherman (1996) showed this same size for the bias of $\hat{\tau}_{n,OL}^2$ with sampling regions based on rectangles $R_0 = (-1/2,1/2)^d$ or simple closed curves in $\mathbb{R}^2$, respectively. Lemma 4.1 extends these results to a broader class of sampling regions. However, we would like to precisely identify the
\(O(1/\lambda_n)\) bias component for \(\hat{\sigma}_{n,OL}^2\) or \(\hat{\sigma}_{n,NOL}^2\) to later obtain theoretically correct proportionality constants associated with optimal subsample scaling.

To achieve some measure of success in determining the exact bias of the subsampling estimators, we reformulate the subsampling design slightly so that \(s\lambda_n = s\lambda_1^{(n)} = \cdots = s\lambda_d^{(n)}\). That is, a common scaling factor in all directions is now used to define the subsampling regions (as in Sherman and Carlstein (1994); Sherman (1996)). This constraint will allow us to deal with the counting issues at the heart of the bias expansion.

Adopting a common scaling factor \(s\lambda_n\) for the subsamples also is sensible for a few other reasons at this stage:

- "Unconstrained" optimum values of \(s\Delta_n\) cannot always be found by minimizing the asymptotic MSE of \(\hat{\sigma}_{n,OL}^2\) or \(\hat{\sigma}_{n,NOL}^2\), even for variance estimation of some desirable statistics on geometrically "simple" sampling and subsampling regions. Consider estimating the variance of a real-valued sample mean over a rectangular sampling region in \(\mathbb{R}^d\) based on \(R_0 = (-1/2, 1/2)^d\), with observations on \(Z^d = \mathbb{Z}^d\). If Assumptions A.1-A.5 and Condition \(M_1\) hold, the leading term in the bias expansion can be shown to be:

\[
\text{Bias of } \hat{\sigma}_{n,OL}^2 = \left(-\sum_{i=1}^{d} \frac{L_i}{s\lambda_i^{(n)}}\right) (1 + o(1)); \quad L_i = \sum_{\mathbf{k} \in \mathbb{Z}^d} |k_i| \text{Cov}(Z(0), Z(k)).
\]

In using the parenthetical sum above to expand the MSE of \(\hat{\sigma}_{n,OL}^2\), one finds that the resulting MSE cannot be minimized over the permissible, positive range of \(s\Delta_n\) if the signs of the \(L_i\) values are unequal. That is, for \(d > 1\), the subsample estimator MSE cannot always be globally minimized to obtain optimal subsample factors \(s\Delta_n\) by considering just the leading order bias terms. An effort to determine and incorporate (into the asymptotic MSE) second or third order bias components quickly becomes intractable, even with rectangular regions.

- The diagonal components of \(s\Delta_n\) are asymptotically scalar multiples of each other by Assumption A.1. If so desired, a template choice for \(R_0\) could be used to scale the expansion of the subsampling regions in each direction.

In the continued discussion, we assume

\[sR_n = s\lambda_nR_0.\] \hspace{1cm} (4.1)

We frame the components necessary for determining the biases of the spatial subsample variance estimators in the next theorem. Let \(C_n(k) \equiv |Z^d \cap sR_n \cap (k + sR_n)|\) denote the number of pairs of observations in the subsampling region \(sR_n\), separated by a translate \(k \in \mathbb{Z}^d\).

**Theorem 4.1** Suppose that \(d \geq 2\), \(sR_n = s\lambda_nR_0\) and Assumptions A.1 - A.5, Conditions D_3 and M_3+a hold. If, in addition, \(s\lambda_n \in \mathbb{Z}_+\) for NOL subsamples and

\[
\lim_{n \to \infty} \frac{sN_n - C_n(k)}{(s\lambda_n)^{d-1}} = C(k) \hspace{1cm} (4.2)
\]

exists for all \(k \in \mathbb{Z}^d\), then

\[
E(\hat{\sigma}_n^2) - \sigma_n^2 = \frac{-1}{s\lambda_n R_0} \left( \sum_{k \in \mathbb{Z}^d} C(k) \sigma(k) \right) (1 + o(1))
\]
where $\sigma(\mathbf{k}) = \text{Cov} \left( \nabla' Z(\mathbf{t}), \nabla' Z(\mathbf{t} + \mathbf{k}) \right)$ and where $\hat{\tau}^2_n$ is either $\hat{\tau}^2_{n,\text{OL}}$ or $\hat{\tau}^2_{n,\text{NOL}}$.

Note that the numerator on the left side of (4.2) is the number of integer grid points that lie in the subregion $\mathcal{J}_R$, but not in the translate $\mathbf{k} + \mathbf{R}_n$. Hence, computing the bias above actually requires counting the number of lattice points inside intersections like $\mathcal{J}_R \cap (\mathbf{k} + \mathbf{R}_n)$, which is difficult in general. To handle this problem, one may attempt to estimate the count $C_n(\mathbf{k})$ with the corresponding Lebesgue volume, $|\mathcal{J}_R \cap (\mathbf{k} + \mathbf{R}_n)|$, and then quantify the resulting approximation error. The determination of volumes or areas may not be easy either but hopefully more manageable. For example, if $R_0$ is a circle, the area of $\lambda_n R_0$ can be readily computed, but the number of $\mathbb{Z}^2$ integers inside $\lambda_n R_0$ is not so simple and was in fact a famous consideration of Gauss [cf. Krätzel (1988, p. 141)].

We first note that the boundary condition on $R_0$ provides a general (trivial) bound on the discrepancy between the count $C_n(\mathbf{k})$ and the volume $|\mathcal{J}_R \cap (\mathbf{k} + \mathbf{R}_n)|$: $O(\lambda_n^{d-1})$. However, the size of the numerator in (4.2) is also $O(\lambda_n^{d-1})$, corresponding to the order of $\mathbb{Z}^d$ lattice points “near” the boundary of $\mathcal{J}_R$. Consequently, a standard $O(\lambda_n^{d-1})$ bound on the volume-count approximation error is too large to immediately justify the exchange of volumes $|\mathcal{J}_R|$, $|\mathcal{J}_R \cap (\mathbf{k} + \mathbf{R}_n)|$ for counts $\lambda_n C_n(\mathbf{k})$ in (4.2).

Bounds on the difference between lattice point counts and volumes have received much attention in analytic number theory, which we briefly mention. Research has classically focused on sets outlined by “smooth” simple closed curves in the plane $\mathbb{R}^2$ and on one question in particular [Huxley (1996)]: When a curve with interior area $A$ is ‘blown up’ by a factor $b$, how large is the difference between the number of $\mathbb{Z}^2$ integer points inside the new curve and the area $b^2 A$? For convex sets with a smoothly winding border, van der Corput’s (192) answer to the posed question above is $O(b^{6/7+\epsilon})$, while the best answer is $O(b^{6/7+\epsilon})$ for curves with sufficiently differentiable radius of curvature [Huxley (1993, 1996)]. These types of bounds, however, are invalid for many convex polygonal templates $R_0$ in $\mathbb{R}^2$ such as triangles, trapezoids, etc., where often the difference between number of $\mathbb{Z}^2$ integer points in $\mathcal{J}_R = \lambda_n R_0$ and its area is of exact order $O(\lambda_n)$ (set also by the boundary condition on $R_0$ or the perimeter length of $\mathcal{J}_R$). The problem above, as considered by number theorists, does not directly address counts for intersections between an expanding region and its vector translates, e.g. $\mathcal{J}_R \cap (\mathbf{k} + \mathbf{R}_n)$.

To eventually compute “closed-form” bias expansions for $\hat{\tau}^2_{n,\text{NOL}}$, we use approximation techniques for subtracted lattice point counts. For each $\mathbf{k} \in \mathbb{Z}^d$, we

1. replace the numerator of (4.2) with the difference of corresponding Lebesgue volumes.
2. show the following error term is of sufficiently small order $O(\lambda_n^{d-1})$:

$$
\left( \lambda_n C_n(\mathbf{k}) \right) - \left( \lambda_n^d |R_0| - |\mathcal{J}_R \cap (\mathbf{k} + \mathbf{R}_n)| \right) = \left( \lambda_n C_n(\mathbf{k}) - \lambda_n^d |R_0| \right) - \left( \lambda_n C_n(\mathbf{k}) - |\mathcal{J}_R \cap (\mathbf{k} + \mathbf{R}_n)| \right).
$$

We do approximate the number of lattice points in $\mathcal{J}_R$ and $\mathcal{J}_R \cap (\mathbf{k} + \mathbf{R}_n)$ by set volumes, though the Lebesgue volume may not adequately capture the lattice point count in either set. However, the difference between approximation errors $|\lambda_n C_n(\mathbf{k}) - \lambda_n^d |R_0|$ and $\lambda_n C_n(\mathbf{k}) - \lambda_n C_n(\mathbf{k})$ can be shown to be asymptotically small enough, for some templates $R_0$, to justify replacing counts with volumes in (4.2) (see Lemma 9.4). That is, these two volume-count estimation errors can cancel to a sufficient extent when subtracted. The above approach becomes slightly more complicated for NOL subsamples, $\mathcal{J}_{R_0} = \Delta_n (1 + R_0)$, which may vary in number of sampling sites $\lambda_n$. In this case, errors incurred by approximating counts $|\mathbb{Z}^d \cap (\mathcal{J}_{R_0} \cap (\mathbf{k} + \mathcal{J}_{R_0}))$ with volumes $|\mathcal{J}_{R_0} \cap (\mathbf{k} + \mathcal{J}_{R_0})|$ are shown to be asymptotically negligible, uniformly in $i \in J_{NOL}$. 

12
In the following theorem, we use this technique to give bias expansions for a large class of sampling regions in $\mathbb{R}^d$, $d \leq 3$, which are “nearly” convex. That is, the sampling region $R_n$ differs from a convex set possibly only at its boundary, but sampling sites on the border may be arbitrarily included or excluded from $R_n$.

Some notation is additionally required. For $\alpha = (\alpha_1, \ldots, \alpha_p)' \in (\mathbb{Z}_+)^p$, $x \in \mathbb{R}^p$, write $x^\alpha = \prod_{i=1}^p x_i^{\alpha_i}$, $\alpha! = \prod_{i=1}^p (\alpha_i)!$, and $c_\alpha = D^\alpha H(\mu)/\alpha!$. Let $Z_\infty$ denote a random vector with a normal $\mathcal{N}(0, \Sigma_\infty)$ distribution on $\mathbb{R}^p$, where $\Sigma_\infty$ is the limiting covariance matrix of the scaled sample mean $\sqrt{n} \tilde{Z}_n - \mu$ from (2.1). Let $B^*, \overline{B}$ denote the interior and closure of $B \in \mathbb{R}^d$, respectively.

**Theorem 4.2** Suppose $sR_n = s\lambda_n R_0$ and there exists a convex set $B$ such that $B^* \subset R_0 \subset \overline{B}$. With Assumptions A.2 - A.5, assume Conditions $D_{d-\delta}$ and $M_{d-\delta-\alpha}$ hold for $d \in \{1, 2, 3\}$. Then,

$$C(k) = V(k) \equiv \lim_{n \to \infty} \frac{|sR_n| - |sR_n \cap (k + sR_n)|}{(s\lambda_n)^{d-1}}, \quad k \in \mathbb{Z}^d$$

whenever $V(k)$ exists and the biases $E(\tau^2_{n,OL}) - \tau^2_n$, $E(\tau^2_{n,NOL}) - \tau^2_n$ are equal to:

for $d = 1$,

$$-\frac{1}{s\lambda_n|R_0|} \left( \sum_{k \in \mathbb{Z}} |k| \sigma(k) + C_\infty \right) (1 + o(1))$$

for $d = 2$ or 3,

$$-\frac{1}{s\lambda_n|R_0|} \left( \sum_{k \in \mathbb{Z}^d} |k| \sigma(k) \right) (1 + o(1))$$

or

$$-\frac{1}{s\lambda_n|R_0|} \left( \sum_{k \in \mathbb{Z}^d} V(k) \sigma(k) \right) (1 + o(1)), \quad \text{provided each } V(k) \text{ exists};$$

where $\sigma(k) = \text{Cov}(\nabla' Z(t), \nabla' Z(t+k))$ and $C_\infty = \text{Var} \left( \sum_{||\alpha||=2} \frac{c_\alpha}{\alpha!} Z_\infty^{\alpha} + 2 \sum_{||\alpha||=1, ||\beta||=3} \frac{c_\alpha c_\beta}{\beta!} E \left( Z_\infty^\alpha Z_\infty^\beta \right) \right)$

$$+ 2 \sum_{k_1, k_2 \in \mathbb{Z}} \sum_{||\alpha||=1, \beta=1} \frac{c_\alpha c_0 (\beta+\gamma)!}{\beta!} \left( Z(t) - \mu \right)^\alpha \left( Z(t + k_1) - \mu \right)^\beta \left( Z(t + k_2) - \mu \right)^\gamma$$

**Remark 1:** If Condition $D_x$ holds with $C = 0$ for $x \in \{2, 3, 4\}$, then Condition $M_{x-1}$ is sufficient in Theorem 4.2.

**Remark 2:** For each $k \in \mathbb{Z}^d$, the numerator in $V(k)$ is of order $O(s \lambda_n^{d-1})$ by the $R_\Gamma$-boundary condition which holds for convex templates. We may then expand the bias of the estimators through the limiting, scaled volume differences $V(k)$. For $d = 1$, with samples and subsamples based on intervals, it can be easily seen that $V(k) = |k|$ which appears in Theorem 4.2.

The function $H(\cdot)$ needs to be increasingly “smoother” to determine the bias component of $\tau^2_{n,OL}$ or $\tau^2_{n,NOL}$ in lower dimensional spaces $d = 1$ or 2. For a real-valued time series sample
mean \( \hat{\theta}_n = \bar{Z}_n \), the well-known bias of the subsample variance estimators follows from Theorem 4.2 under our sampling framework \( R_0 = (-1/2, 1/2] \), \( Z = Z \):

\[
\frac{-1}{\lambda_n} \left( \sum_{k \in Z} |k| \text{Cov} \left( \nabla Z(0), \nabla Z(k) \right) \right)
\]

(4.3)

with \( \nabla = 1 \). In general though, terms in the Taylor expansion of \( \hat{\theta}_{1,n} \) (around \( \mu \)) up to fourth order can contribute to the bias of \( \hat{\tau}^2_{n,0,0} \) and \( \hat{\tau}^2_{n,NOL} \) when \( d = 1 \). In contrast, the asymptotic bias of the time series MBB variance estimator with “smooth” model statistics is very different from its subsample-based counterpart. The MBB variance estimator’s bias is given by (4.3), determined only by the linear component from the Taylor’s expansion of \( \hat{\theta}_{1,n} \) [cf. Lahiri (1996)].

5 Asymptotically optimal subsample sizes

In the following, we consider “size” selection for the subsampling regions to maximize the large-sample accuracy of the subsample variance estimators. For reasons discussed in Section 4, we examine a theoretically optimal scaling choice \( \lambda_n \) for subregions in (4.1).

5.1 Theoretical optimal subsample sizes

Generally speaking, there is a trade off in the effect of subsample size on the bias and variance of \( \hat{\tau}^2_{n,0,0} \) or \( \hat{\tau}^2_{n,NOL} \). For example, increasing \( \lambda_n \) reduces the bias but increases the variance of the estimators. The best value of \( \lambda_n \) optimizes the over-all performance of a subsample variance estimator by balancing the contributions from both the estimator’s variance and bias. An optimal \( \lambda_n \) choice can be found by minimizing the asymptotic order of a variance estimator’s MSE under a given OL or NOL sampling scheme.

Theorem 4.1 implies that the bias of the estimators \( \hat{\tau}^2_{n,0,0} \) and \( \hat{\tau}^2_{n,NOL} \) is of exact order \( O(1/\lambda_n) \). For a broad class of sampling regions \( R_n \), the leading order bias component can be determined explicitly with Theorem 4.2. We bring these variance and bias expansions together to obtain an optimal subsample scaling factor \( \lambda_n \).

Theorem 5.1 Let \( sR_n = \lambda_n R_0 \). With Assumptions A.2 - A.5, assume Conditions D_2 and M_{5+2a} hold if \( d \geq 2 \); and Conditions D_3 and D_{7+2a} if \( d = 1 \). If \( B_0 \equiv |R_0|^{-1} \sum_{k \in Z^d} C(k) \sigma(k) \neq 0 \), then

\[
s^{\lambda_n}_{n,0,0} = \left( \frac{\text{det}(\Delta_n)(B_0)^2}{dK_0 \tau^4} \right)^{1/(d+2)} (1 + o(1)) \text{ and } s^{\lambda_n}_{n,NOL} = \left( \frac{\text{det}(\Delta_n)(B_0)^2}{dK_0 \tau^4} \right)^{1/(d+2)} (1 + o(1)).
\]

Remark 3: If Condition D_2 holds with \( C = 0 \) for \( x \in \{2, 3\} \), then Condition M_{2x-1} is sufficient.

Remark 4: Theorem 5.1 suggests that optimally scaled OL subsamples should be larger than the NOL ones by a scalar: \( (K_1)^{-1/(d+2)} > 1 \) where \( K_1 = K_0|R_0| \) the limiting ratio of variances from (3.1).

It is well-known in the time series case that the OL subsampling scheme produces an asymptotically more efficient variance estimator than its NOL counterpart. We can now quantify the relative efficiency of the two subsampling procedures in \( d \)-dimensional sampling space. With each
variance estimator respectively optimized using (4.1), \( \hat{\tau}^2_{\text{opt}_n} \) is more efficient than \( \hat{\tau}^2_{\text{NOL}_n} \) and the asymptotic relative efficiency of \( \hat{\tau}^2_{\text{NOL}_n} \) to \( \hat{\tau}^2_{\text{opt}_n} \) depends solely of the geometry of \( R_0 \):

\[
ARE_d = \lim_{n \to \infty} \frac{\text{E}(\hat{\tau}^2_{\text{opt}_n} - \hat{\tau}^2_{\text{NOL}_n})^2}{\text{E}(\hat{\tau}^2_{\text{NOL}_n} - \hat{\tau}^2_{\text{opt}_n})^2} = (K_1)^{2/(d+2)} < 1.
\]

Possolo (1991), Politis and Romano (1993a, 1994), Hall and Jing (1996), and Garcia-Soidan and Hall (1997) have examined subsampling with rectangular regions based essentially on \( R_0 = (-1/2, 1/2)^d \). Using the geometrical characteristic \( K_1 = (\pi^d)^{d/2} \) for rectangles, we can now examine the effect of the sampling dimension on the \( ARE_d \) of \( \hat{\tau}^2_{\text{NOL}_n} \) to \( \hat{\tau}^2_{\text{opt}_n} \) for these sampling regions. Although the \( ARE_d \) decreases as the dimension \( d \) increases, we find the relative improvement of \( \hat{\tau}^2_{\text{opt}_n} \) over \( \hat{\tau}^2_{\text{NOL}_n} \) is ultimately limited and the \( ARE_d \) has a lower bound of 4/9 for all \( \mathbb{IR}^d \)-rectangular regions.

6 Examples

We now provide some examples of the important quantities \( K_0, K_1, B_0 \) associated with optimal scaling \( \lambda_n^{\text{opt}} \) with some common sampling region templates, determined from Theorems 3.1 and 4.2. For subsamples from (4.1), the theoretically best \( \lambda_n^{\text{opt}} \) can also be formulated in terms of \( |R_n| = \text{det}(\Delta_n)|R_0| \) (sampling region volume), \( K_1 \), and \( B_0 \).

6.1 Examples in \( \mathbb{IR}^2 \)

example 1. Rectangular regions in \( \mathbb{IR}^2 \) (potentially rotated):

If \( R_0 = \left\{ ((l_1 \cos \theta, l_2 \sin \theta)x, (-l_1 \sin \theta, l_2 \cos \theta)x) : x \in (-1/2, 1/2]^2 \right\} \) for \( \theta \in [0, \pi], 0 < l_1, l_2 \), then

\[
K_0 = \frac{4}{9}, \quad B_0 = \sum_{k = (k_1, k_2)^T} \left( \frac{|k_1 \cos \theta - k_2 \sin \theta|}{l_1} + \frac{|k_1 \sin \theta + k_2 \cos \theta|}{l_2} \right) \sigma(k).
\]

The characteristics \( K_1, B_0 \) for determining optimal subsamples based on two rectangular templates are further described in Table 4.

example 2. If \( R_0 \) is a circle of radius \( r \leq 1/2 \) centered at the origin, then \( K_0 \) appears in Table 3 and \( B_0 = 2/(\pi r) \sum_{k \in \mathbb{Z}^2} \|k\| \sigma(k) \).

example 3. For any triangle, \( K_0 = 2/5 \). Two examples are provided in Tables 2 and 4.

example 4. For any parallelogram in \( \mathbb{IR}^2 \) with interior angle \( \gamma \) and adjacent sides of ratio \( b \geq 1 \), \( K_0 = 4/9 + 2/15 \cdot b^{-2}[\cos \gamma(1 - |\cos \gamma|)] \). In particular, if a parallelogram \( R_0 \) is formed by two vectors \((0, l_1), (l_2 \cos \gamma, l_2 \sin \gamma)^T \) extended from a point \( x \in (-1/2, 1/2]^2 \), then

\[
B_0 = \frac{1}{\sin \gamma} \sum_{k \in \mathbb{Z}^2} \left( \frac{|k_1 \cdot \cos \gamma - k_2 \cdot \sin \gamma|}{\max\{l_1, l_2\}} + \frac{|k_2|}{\min\{l_1, l_2\}} \right) \sigma(k), \quad \gamma \in (0, \pi), l_1, l_2 > 0.
\]

For further bias term \( B_0 \) calculation tools with more general (non-convex) sampling regions and templates \( R_0 \) (represented as the union of two approximately convex sets), see Nordman (2002).
Table 4: Examples of several shapes of $R_0 \subset \mathbb{R}^2$ and associated $K_1$, $B_0$ for $\lambda_{opt}^d$.

Figure 1. Examples of templates $R_0 \subset (-1/2, 1/2]^2$ are outlined by solid lines. Cross-shaped sampling regions $R_n$ described in Table 2 are based on $R_0$ in (v).

6.2 Examples in $\mathbb{R}^d$, $d \geq 3$

**Example 5.** For any sphere, $K_0$ is given in Table 3. The properties $B_0$, $K_1$ of the sphere described in Table 1 and 2 correspond to the template sphere $R_0$ of radius 1/2 (and maximal volume in $(-1/2, 1/2]^3$).

**Example 6.** The $K_0$ value for any $\mathbb{R}^3$ cylinder appears in Table 3. If $R_0$ is a cylinder with circular base (parallel to $x$-$y$ plane) of radius $r$ and height $h$, then

$$B_0 = \sum_{k \in \mathbb{Z}^2, \|k\| \leq h/2} \left( \frac{|k_3|}{h} + \frac{2\sqrt{k_1^2 + k_2^2}}{\pi r} \right) \sigma(k).$$

The results of Theorem 4.2 for determining the bias $B_0$ also seem plausible for convex sampling regions in $\mathbb{R}^d$, $d \geq 4$, but require further study of lattice point counting techniques in higher dimensions. However, bias expansions of the OL and NOL subsample variance estimators are relatively straightforward for an important class of rectangular sampling regions based on the prototype $R_0 = (-1/2, 1/2]^d$, which can then be used in optimal subsample scaling. These hypercubes have “faces” parallel to the coordinate axes which simplifies the task of counting sampling sites, or lattice points, within such regions. We give precise bias expansions in the following theorem, while allowing for potentially missing sampling sites at the borders, or faces, of the sampling region $R_n$. 

16
Theorem 6.1 Let \((-1/2, 1/2)^d \subset \Lambda^{-1}\Lambda_0 \subset [-1/2, 1/2]^d\), \(d \geq 3\) for a \(d \times d\) diagonal matrix \(\Lambda_0\) with entries 0 \(<\ell_i \leq 1\), \(i = 1, \ldots, d\). Suppose \(R_n = s\lambda_n R_0\) and Assumptions A.2 - A.5, Conditions D2 and \(M_{2+n}\) hold. Then, the biases \(E(\hat{\tau}_{n,\text{OL}}^2) - \tau_n^2\), \(E(\hat{\tau}_{n,\text{NOL}}^2) - \tau_n^2\) are equal to 
\[-s\lambda^{-1}_n B_0(1 + o(1))\] 
where

\[
B_0 = \sum_{k \in \mathbb{Z}^d} \left( \sum_{i=1}^d \frac{|k_i|}{\ell_i} \right) \sigma(k), \quad \sigma(k) = \text{Cov}(\nabla' Z(t), \nabla' Z(t + k)).
\]

Example 7. For rectangular sampling regions \(R_n = \Delta_n (-1/2, 1/2)^d\), optimal subsamples may be chosen with 

\[
s\lambda_{n,\text{NOL}}^\text{opt} = \left( \frac{\|R_n\|}{\sum_{k \in \mathbb{Z}^d} \|k\| \sigma(k)} \right)^{1/(d+2)} \left( 1 + o(1) \right) \quad \text{or} \quad s\lambda_{n,\text{OL}}^\text{opt} = s\lambda_{n,\text{NOL}}^\text{opt} \left( \frac{3}{2} \right)^{1/(d+2)}
\]

(common directional scaling) using the template \(R_0 = (-1/2, 1/2)^d\).

7 Empirical subsample size determination

In this section we consider data-based estimation of the theoretical optimal subsample sizes. In particular, we propose methods for estimating the scaling factor \(s\lambda^\text{opt}_n\) for subsamples in (4.1), which are applicable to both OL and NOL subsampling schemes. Inference on “best” subsample scaling closely resembles the problem of empirically gauging the theoretically optimal block size with the MBB variance estimator, which has been much considered for time series. We first frame the techniques used in this special setting, which can be modified for data-based subsample selection.

Two distinct techniques have emerged for estimating the (time series) MBB block size. One approach involves “plug-in” type estimators of optimal block length [cf. Bühlmann and Künsch (1999)]. For subsample inference on \(n\text{Var}(\hat{Z}_n)\), Carlstein (1986) (with AR(1) models) and Politis et al. (1999) have described “plug-in” estimators for subsample length. The second MBB block selection method, suggested by Hall et al. (1995) and Hall and Jing (1996), uses subsampling to create a data-based version of the MSE of the MBB estimator (as a function of block size) which then is minimized to obtain an estimate of optimal block length. With spatial data, Garcia-Soledan and Hall (1997) extended this empirical MSE selection procedure with subsample-based distribution estimators. For variance estimation of a univariate time series sample mean, Lèger et al. (1992) proposed a subsample length estimate based on asymptotic MSE considerations; namely, selecting a size by simultaneously solving \((s\lambda^\text{opt}_n)^3 = (3/2)(\hat{B}/\hat{\tau}_{n,\text{OL}}^2)^2 n\) for \(s\lambda^\text{opt}_n\) and the associated estimator \(\hat{\tau}_{n,\text{OL}}^2\), where \(\hat{B}\) estimates the parenthetical quantity in (4.3).

A “plug-in” procedure for inference on the theoretical, optimal subsample size involves constructing, and subsequently substituting, (consistent) estimates of unknown population parameters in \(s\lambda^\text{opt}_n\) from Theorem 5.1. The limiting variance \(\hat{\tau}^2\) appears in the formulation of \(s\lambda^\text{opt}_n\) and could be approximated with a subsample variance estimate based on some preliminary size choice. The value \(K_0\) can be determined from the available sampling region \(R_n\), but selection of a template \(R_0\) is also required in the “plug-in” approach. The best solution may be to pick a sampling template \(R_0\) to be the largest set of the form \(\Lambda^{-1}\Lambda_0\) for a positive diagonal matrix \(\Lambda\) that fits within \((-1/2, 1/2)^d\); this choice appears to reduce the magnitude of the bias of \(\hat{\tau}_{n,\text{OL}}^2\), \(\hat{\tau}_{n,\text{NOL}}^2\), which contributes heavily to the MSE of an estimator.
In a spirit similar to the “plug-in” approach, one could empirically select \( \lambda_{n,OL} \) as in Lèger et al. (1992) and Politis and Romano (1993b). After evaluating \( K_0 \) and an estimate \( \hat{B}_0 \) of the leading bias component \( B_0 \), compute \( \hat{\tau}^2_{n,OL} \) (or analogously \( \hat{\tau}^2_{n,NOL} \)) for a series of \( \lambda_n \) values and simultaneously solve the asymptotical MSE-based formulation

\[
\lambda_n \hat{\tau}^2 = \text{det}(\Delta_n)(\hat{B}_0)^2/(dK_0(\hat{\tau}^2_{n,OL})^2)
\]

for \( \lambda_n \) and an associated \( \hat{\tau}^2_{n,OL} \).

8 Proofs for variance expansions

For the proofs, we use \( C \) to denote generic positive constants that do not depend on \( n \) or any \( \mathbb{Z}^d \) integers (or \( \mathbb{Z}^d \) lattice points). The real number \( r \), appearing in some proofs, always assumes the value stated under Condition \( M_r \) with respect to the lemma or theorem under consideration. Unless otherwise specified, limits in order symbols are taken letting \( n \) tend to infinity.

In the following, we denote the indicator function as \( I_{\{ \cdot \}} \) (i.e., \( I_{\{ \cdot \}} \in \{0, 1\} \) and \( I_{\{ A \}} = 1 \) if and only if an event \( A \) holds). For two sequences \( \{a_n\} \) and \( \{b_n\} \) of positive real numbers, we write \( a_n \sim b_n \) if \( a_n/b_n \to 1 \) as \( n \to \infty \). We write \( \Delta_n^{\text{max}} \) and \( \Delta_n^{\text{max}} \) for the largest diagonal entries of \( \Delta_n \) and \( \Delta_n \), respectively, while \( \Delta_n^{\text{max}} \geq 1 \) will denote the smallest diagonal entry of \( \Delta_n \).

We require a few lemmas for the proofs.

**Lemma 8.1** Suppose \( T_1, T_2 \subset \mathbb{Z}^d \equiv \mathbf{t} + \mathbb{Z}^d \) are bounded. Let \( p, q > 0 \) where \( 1/p + 1/q < 1 \). If \( X_1, X_2 \) are random variables, with \( X_i \) measurable with respect to \( \mathcal{F}_T(T_i), i = 1, 2 \), then

\[
|\text{Cov}(X_1, X_2)| \leq (E|X_i|^p)^{1/p} (E|X_i|^q)^{1/q} \alpha \left( \text{dis}(T_1, T_2); \max_{i=1,2} |T_i| \right)^{1-1/p-1/q},
\]

provided expectations are finite and \( \text{dis}(T_1, T_2) > 0 \).

*Proof.* Follows from Theorem 3, Doukhan (1994, p. 9). \( \square \)

**Lemma 8.2** Let \( r \in \mathbb{Z}_+ \). Under Assumption A.3 and Condition \( M_r \), for \( 1 \leq m \leq 2r \) and any \( T \subset \mathbb{Z}^d \equiv \mathbf{t} + \mathbb{Z}^d \),

\[
E \left\| \sum_{\mathbf{s} \in T} (Z(\mathbf{s}) - \mu) \right\|^m \leq C(\alpha)|T|^{m/2};
\]

\( C(\alpha) \) is a constant that depends only on the coefficients \( \alpha(k, l), l \leq 2r, \) and \( E\|Z(\mathbf{t})\|^{2r+\delta} \).

*Proof.* This follows from Theorem 1, Doukhan (1994, p. 26-31) and Jensen’s inequality. \( \square \)

We next determine the asymptotic sizes of important sets relevant to the sampling or subsampling designs.

**Lemma 8.3** Under Assumptions A.1-A.2, the number of sampling sites within

(a) the sampling region \( R_n \), \( N_n = |R_n \cap \mathbb{Z}^d| \sim |R_0| \cdot \text{det}(\Delta_n) \);

(b) an OL subsample, \( R_{i,\text{OL}} \), \( i \in J_{\text{OL}} : |N_{i,\text{OL}}| \sim |R_0| \cdot \text{det}(\Delta_n) \);

(c) a NOL subsample, \( R_{i,\text{NOL}} \), \( i \in J_{\text{NOL}} : |N_{i,\text{NOL}}| \sim |R_0| \cdot \text{det}(\Delta_n) \).

The number of

(d) OL subsamples within \( R_n \), \( |J_{\text{OL}}| \sim |R_0| \cdot \text{det}(\Delta_n) \);

(e) NOL subsamples within \( R_n \), \( |J_{\text{NOL}}| \sim |R_0| \cdot \text{det}(\Delta_n) \cdot \text{det}(\Delta_n)^{-1} \).

(f) sampling sites near the border of a sample, \( R_n \) or \( \bar{R}_{i,\text{OL}} \), is less than

\[
\sup_{\mathbf{u} \in \mathbb{Z}^d} |\{ j \in \mathbb{Z}^d : T_\mathbf{u} \cap \bar{R}_{i,\text{OL}} \neq \emptyset, T_\mathbf{u} \cap \bar{R}_{i,\text{OL}} \neq \emptyset \text{ for } T_\mathbf{u} = j + [-2, 2]^d \}| \leq C(\lambda^{\text{max}})^{d-1}.
\]

*Proof.* Results follow from the boundary condition on \( R_0 \); see Nordman (2002) for more details.
We require the next lemma for counting the number of subsampling regions which are separated by an appropriately “small” integer translate; we shall apply this lemma in the proof of Theorem 3.1. For \( k = (k_1, \ldots, k_d)^t \in \mathbb{Z}^d \), define the following sets,

\[
J_n(k) = \{ i \in J_{ol} : i + k + s\Delta_n R_0 \subset R_n \}, \quad E_n = \{ k \in \mathbb{Z}^d : |k_j| \leq s\lambda_j^{-1}, \ j = 1, \ldots, d \}.
\]

**Lemma 8.4** Under Assumption A.2,

\[
\max_{k \in E_n} \left| \frac{J_n(k)}{|J_{ol}|} - 1 \right| = o(1).
\]

**Proof:** For \( k \in E_n \), write the set \( J_n^*(k) \) and bound its cardinality:

\[
J_n^*(k) = |\{ i \in J_{ol} : (i + k + s\Delta_n R_0) \cap \Delta_n R_0^c \neq \emptyset \} | \leq |\{ i \in \mathbb{Z}^d : T^d \cap \Delta_n R_0^c \neq \emptyset, T^d \cap \Delta_n R_0^c \neq \emptyset \} | \leq C_s \lambda_n^\alpha (\lambda_n^\alpha)^d - 1,
\]

by the boundary condition on \( R_0 \). We have then that for all \( k \in E_n \),

\[
|J_n^*| \geq J_n(k) = |J_{ol}| - J_n^*(k) \geq |J_{ol}| - C_s \lambda_n^\alpha (\lambda_n^\alpha)^d - 1.
\]

By Assumption A.2 and the growth rate of \( |J_{ol}| \) from Lemma 8.3, the proof is complete. \( \square \)

We now provide a theorem which captures the main contribution to the asymptotic variance expansion of the OL subsample variance estimator \( \tilde{\tau}^2_{n, ol} \) from Theorem 3.1.

**Theorem 8.1** For \( \mathbf{i} \in \mathbb{Z}^d \), let \( Y_{1,n} = \nabla' (Z_{4,n} - \mu) \). Under the Assumptions and Conditions of Theorem 3.1,

\[
sn_{n} \sum_{k \in E_n} \text{Cov}(Y_{0,n}^2, Y_{k,n}^2) = K_0 \cdot [2\tau_d](1 + o(1)),
\]

where the constant \( K_0 \) is defined in Theorem 3.1.

**Proof:** We give only a sketch of the important features; for more details, see Nordman (2002). For a set \( T \subset \mathbb{R}^d \), define the function \( \Sigma(\cdot) \) as

\[
\Sigma(T) = \sum_{s \in \mathbb{Z}^d \cap T} \nabla'(Z(s) - \mu).
\]

With the set intersection \( R_{k,n}^0 = sR_n \cap (k + sR_n), k \in \mathbb{Z}^d \), write functions:

\[
H_{1,n}(k) = \Sigma(R_{k,n} \setminus R_{k,n}^0), \quad H_{2,n}(k) = \Sigma(R_{0,n} \setminus R_{k,n}^0), \quad H_{3,n}(k) = \Sigma(R_{k,n}^0).
\]

These represent, respectively, sums over sites in: \( R_{k,n} \) but not \( R_{0,n} = sR_n \); \( R_{0,n} \) but not \( R_{k,n} \); and both \( R_{0,n} \) and \( R_{k,n} \). Then define \( h_n(\cdot) : \mathbb{Z}^d \to \mathbb{R} \) as

\[
h_n(k) = E[H_{1,n}(k)] E[H_{2,n}(k)] E[H_{3,n}(k)] + E[H_{1,n}(k)] E[H_{2,n}(k)] E[H_{3,n}(k)] + E[H_{2,n}(k)] E[H_{3,n}(k)] + E[H_{1,n}(k)] - (sn_n)^2 E(Y_{0,n}^2).
\]

We will make use of the following proposition.

**Proposition 8.1** Under the Assumptions and Conditions of Theorem 3.1,

\[
\max_{k \in E_n} \left| (sn_n)^2 \text{Cov}(Y_{0,n}^2, Y_{k,n}^2) - (sn_n)^{-2} h_n(k) \right| = o(1).
\]

19
The proof of Proposition 8.1 can be found in Nordman (2002) and involves cutting out $\mathbb{Z}^d$ lattice points near the borders of $R_{0,n}$ and $R_{k,n}$, (say) $B_{0,n}^d$ and $B_{k,n}^d$ with

$$\ell_n = \left[ (\lambda_{\min}^{(n)})^\epsilon \right], \quad B_{j,n} = \{i \in \mathbb{Z}^d : i \in \overline{B_{j,n}}, (i + \ell_n(-1, 1)^d) \cap \overline{B_{j,n}} \not= \emptyset \}, \quad j \in \mathbb{Z}^d,$$

where $\epsilon = (\sqrt{\delta}/(2r+\delta)(2r-1-1/d)) + 1/2 < 1$ from Condition $M_r$. Here $\ell_n \to \infty$, $\ell_n = \omega(\lambda_{\min}^{(n)})$ is chosen so that the remaining observations in $R_{0,n}, R_{k,n}, R_{0,n}^U$, are nearly independent upon removing $B_{0,n}, B_{k,n}$ points and, using the $R_0$-boundary condition, the set cardinalities $|B_{0,n}|, |B_{k,n}| \leq C\ell_n(\lambda_{\min}^{(n)})^{-d-1}$ are of smaller order than $\sigma N_n$ (namely, these sets are asymptotically negligible in size).

By Proposition 8.1 and $|E_n| = O(\sigma N_n)$, we have

$$\left| \sum_{k \in E_n} \text{Cov}(Y_{0,n}^2, Y_{k,n}^2) - (\sigma N_n)^{-3} \sum_{k \in E_n} h_n(k) \right| = o(1). \quad (8.1)$$

Consequently, we need only focus on $(\sigma N_n)^{-3} \sum_{k \in E_n} h_n(k)$ to complete the proof of Theorem 8.1.

For measurability reasons, we create a set defined in terms of the $\mathbb{R}^d$ Lebesgue measure:

$$E^+ \equiv (0, 1) \cap \left\{ \epsilon < \frac{\text{det}(\Delta_0)}{2} : \left\{ x \in \mathbb{R}^d : (x + \Delta_0 R_0) \cap \Delta_0 R_0 = \emptyset \text{ or } \text{det}(\Delta_0)|R_0| - \epsilon \right\} = 0 \right\}.$$ 

Note the set \(0 < \epsilon < \min\{1, (\text{det}(\Delta_0)|R_0|)/2 : \epsilon \not\in E^+\} \) is at most countable [cf. Billingsley (1986), Theorem 10.4]. For $\epsilon \in E^+$, define a new set as a function of $\epsilon$ and $n$:

$$\tilde{R}_{t,n} = \{ k \in \mathbb{Z}^d : |R_{k,n}^U| > \epsilon(\lambda_{\min}^{(n)})^d, |\sigma R_n \setminus R_{k,n}^U| > \epsilon(\lambda_{\min}^{(n)})^{-d} \}.$$

Here $\tilde{R}_{t,n} \subseteq E_n$ because $k \not\in E_n$ implies $R_{k,n}^U = \emptyset$.

We now further simplify $(\sigma N_n)^{-3} \sum_{k \in E_n} h_n(k)$ using the following proposition involving $\tilde{R}_{t,n}$.

**Proposition 8.2** There exist $N \in \mathbb{Z}_+$ and a function $b(\cdot) : E^+ \to (0, \infty)$ such that $b(\epsilon) \downarrow 0$ as $\epsilon \downarrow 0$ and

$$(\sigma N_n)^{-3} \left| \sum_{k \in E_n} h_n(k) - \sum_{k \in R_{t,n}} h_n(k) \right| \leq C \left( \epsilon + (\sigma N_n)^{-1} + [b(\epsilon)]^d \right), \quad (8.2)$$

where $C > 0$ does not depend on $\epsilon \in E^+$ or $n \geq N$.

The proof of Proposition 8.2 is tedious and given in Nordman (2002). The argument involves bounding the sum of $h_n(\cdot)$ over two separate sets in $E_n$: those integers in $E_n$ that are either “too large” or “too small” in magnitude to be included in $R_{t,n}$.

To finish the proof, our approach (for an arbitrary $\epsilon \in E^+$) will be to write $(\sigma N_n)^{-3} \sum_{k \in R_{t,n}} h_n(k)$ as an integral of a step function with respect to the Lebesgue measure of a step function, say $f_{\tau_n}(x)$, then show $\lim_{n \to \infty} f_{\tau_n}(x)$ exists almost everywhere (a.e.) on $\mathbb{R}^d$, and apply the Lebesgue Dominated Convergence Theorem (LDCT). By letting $\epsilon \downarrow 0$, we will obtain the limit of $(\sigma N_n)^{-3} \sum_{k \in E_n} \text{Cov}(Y_{0,n}^2, Y_{k,n}^2)$.

Fix $\epsilon \in E^+$. With counting arguments based on the boundary condition of $R_0$ and the definition of $\tilde{R}_{t,n}$, it holds that for some $N_i \in \mathbb{Z}_+$ and all $k \in \tilde{R}_{t,n}$: $|R_{k,n}^U \cap \mathbb{Z}^d| \geq 1$ and $\sigma N_n - |R_{k,n}^U \cap \mathbb{Z}^d| \geq 1$ when $n \geq N_i$. We can rewrite $(\sigma N_n)^{-2} h_n(k), k \in \tilde{R}_{t,n}$, in the well-defined form (for $n \geq N_i$):

$$\frac{h_n(k)}{(\sigma N_n)^2} = E \left[ H_{n,n}^2(k) \right] E \left[ H_{n,n}^2(k) \right] \left( 1 - \frac{|R_{k,n}^U \cap \mathbb{Z}^d|}{\sigma N_n} \right)^2 + \sum_{j=1}^2 E \left[ H_{n,n}^2(k) \right] E \left[ H_{n,n}^2(k) \right] \left( 1 - \frac{|R_{k,n}^U \cap \mathbb{Z}^d|}{\sigma N_n} \right) \left( 1 - \frac{|R_{k,n}^U \cap \mathbb{Z}^d|}{\sigma N_n} \right) + E \left[ H_{n,n}^2(k) \right] \left( \frac{|R_{k,n}^U \cap \mathbb{Z}^d|}{\sigma N_n} \right)^2 - \left[ \sigma N_n E(Y_{0,n}^2) \right]^2.$$
For $x = (x_1, \ldots, x_d)' \in \mathbb{R}^d$, write $|x| = (|x_1|, \ldots, |x_d|)' \in \mathbb{Z}^d$. Let $f_{i,n}(x): \mathbb{R}^d \to \mathbb{R}$ be the step function defined as

$$f_{i,n}(x) = (\nu N_n)^{-2} I_{\{|x| \leq 2, \nu^{-1} h_n(\nu^{-1} |x| ) \}}.$$

We have then that (with the same fixed $\epsilon \in \mathbb{E}^+$):

$$\frac{1}{\nu N_n} \sum_{k \in \tilde{R}_i} (\nu N_n)^{-2} h_n(k) = \left( \frac{\nu^{-1} |x|}{\nu N_n} \right)^d \int_{\mathbb{R}^d} f_{i,n}(x) dx. \quad (8.3)$$

We focus on showing:

$$\lim_{n \to \infty} f_{i,n}(x) = f_i(x) \equiv I_{\{|x| \leq 2\}} \left( \frac{(x + \Delta_0 R_0) \cap \Delta_0 R_0}{\det(\Delta_0)|R_0|} \right)^2 \quad \text{a.e.} \ x \in \mathbb{R}^d, \quad (8.4)$$

with $\tilde{R}_i = \{x \in \mathbb{R}^d : \{(x + \Delta_0 R_0) \cap \Delta_0 R_0 > \epsilon, |\Delta_0 R_0 \setminus (x + \Delta_0 R_0)| > \epsilon\}$, a Borel measurable set.

Write $x_n = (\nu N_n)^{-1} x$, $x \in \mathbb{R}^d$, to ease the notation. To establish (8.4), we begin by showing convergence of indicator functions:

$$I_{\{|x_n| \leq 2, \nu^{-1} h_n(x_n)\}} \to I_{\{|x| \leq 2\}} \quad \text{a.e.} \ x \in \mathbb{R}^d. \quad (8.5)$$

Define the sets $A_n(x) = (\nu N_n)^{-1} \{|x_n + R_n| \cap R_n\} \setminus A_n(x)$ as a function of $x \in \mathbb{R}^d$. The LDCT can be applied to show: for each $x \in \mathbb{R}^d$, $\{A_n(x) \to |(x + \Delta_0 R_0) \cap \Delta_0 R_0| \text{ and } |A_n(x) \to |\Delta_0 R_0 \setminus (x + \Delta_0 R_0)| \}$ if $x \in \tilde{R}_i$, then

$$|A_n(x) \to |(x + \Delta_0 R_0) \cap \Delta_0 R_0| > \epsilon, \quad |A_n(x) \to |\Delta_0 R_0 \setminus (x + \Delta_0 R_0)| > \epsilon, \quad (8.6)$$

implying further that $1 = I_{\{|x_n| \leq 2, \nu^{-1} h_n(x_n)\}} \to I_{\{|x| \leq 2\}} = 1$. Now consider $\tilde{R}_i$. If $x \notin \tilde{R}_i$, such that $|(x + \Delta_0 R_0) \cap \Delta_0 R_0| < \epsilon$ or $|\Delta_0 R_0 \setminus (x + \Delta_0 R_0)| < \epsilon$, then $|A_n(x) < \epsilon$ (or $|A_n(x) > \epsilon$) eventually for large $n$ and $0 = I_{\{|x_n| \leq 2, \nu^{-1} h_n(x_n)\}} \to I_{\{|x| \leq 2\}} = 0$ in this case. Finally, $x \in \mathbb{E}^+$ implies that a last possible subset of $\tilde{R}_i$ has Lebesgue measure zero, namely, $\{x \in \tilde{R}_i : |(x + \Delta_0 R_0) \cap \Delta_0 R_0| = \epsilon \text{ or } |\Delta_0 R_0 \setminus (x + \Delta_0 R_0)| = \epsilon\} = \emptyset$. We have now proven (8.5).

We next establish a limit for $\nu N_n^{-2} h_n(x_n)$, $x \in \tilde{R}_i$. We wish to show:

$$\frac{|R_{x_n}^{z} \cap Z^d|}{\nu N_n} \to \frac{|(x + \Delta_0 R_0) \cap \Delta_0 R_0|}{\det(\Delta_0)|R_0|}, \quad x \in \tilde{R}_i. \quad (8.7)$$

Using the bound $|R_{x_n}^{z} \cap Z^d| \leq C(\nu N_n)^{-d-1}$ from the $R_0$-boundary condition and noting the limit in (8.6), we find: $(\nu N_n)^{-d}|R_{x_n}^{z} \cap Z^d| \to |(x + \Delta_0 R_0) \cap \Delta_0 R_0|, \ x \in \tilde{R}_i$. By this and $(\nu N_n)^{-d}/\nu N_n \to \det(\Delta_0)|R_0|^{-1}$, (8.7) follows.

We can also establish: for each $x \in \tilde{R}_i$, $j = 1$ or 2,

$$E \left[ \frac{H_{x_n}^j(x_n)}{|R_{x_n}^{z} \cap Z^d|} \right] \to E(\nu^j Z^d), \quad E \left[ \frac{H_{x_n}^j(x_n)}{|R_{x_n}^{z} \cap Z^d|} \right], \quad \nu N_n E(\nu^j Z^d) \to E(\nu^j Z^d)^2 \quad (8.8)$$

where $\nu^j Z^d$ is a normal $\mathcal{N}(0, \nu^j)$ random variable and so it follows $E(\nu^j Z^d)^2 = (2j - 1)\nu^j$, $j = 1, 2$. The limits in (8.8) follow essentially from the Central Limit Theorem (CLT) of Böthlauten (1981), after verifying that the CLT can be applied; see Nordman (2002) for more details.

Putting (8.5), (8.7), and (8.8) together, we have shown the (a.e.) convergence of the univariate functions $f_{i,n}(x)$ as in (8.4). For $k \in E_n$ and $n \geq N_r$, Lemma 8.2 ensures: $(\nu N_n)^{-2}|h_n(k)| \leq C$, implying that for $x \in \mathbb{R}^d$: $\int_{E_n} f_{i,n}(x) \leq C f_i(x)$ for some $c > 0$ by Assumption A.1. With this uniform bound on $f_{i,n}(\cdot)$ and the limits in (8.4), we can apply the LDCT to get

$$\lim_{n \to \infty} \int_{\mathbb{R}^d} f_{i,n}(x) dx = \int_{\mathbb{R}^d} f_i(x) dx, \quad \epsilon \in \mathbb{E}^+. \quad (8.9)$$
Let \( \{\epsilon_n\}_{n=1}^{\infty} \subset \mathbb{E}^d \) where \( \epsilon_n \downarrow 0 \). Then, \( \tilde{R}_m \subset \Delta_0[-1,1]^d \) and \( \lim_{m \to \infty} I_{\{x \in \tilde{R}_m\}} \to I_{\{x \in \tilde{R}_0\}} \) for \( x \neq 0 \in \mathbb{R}^d \), with \( \tilde{R}_0 = \{ x \in \mathbb{R}^d : 0 < (x + \Delta_0 R_0) \cap \Delta_0 R_0 < \det(\Delta_0) | R_0 | \} \). Hence, by the LDCT,

\[
\lim_{m \to \infty} \int_{\mathbb{R}^d} f_m(x) \, dx = \int_{\mathbb{R}^d} f_0(x) \, dx, \quad f_0(x) \equiv I_{\{x \in \tilde{R}_0\}} \left( \frac{1}{\det(\Delta_0) | R_0 |} \right)^2.
\]  

(8.10)

From (8.1)-(8.3), (8.9)-(8.10) and \( (\lambda^{|n|})^d \, \mu_n \to (\det(\Delta_0) | R_0 |)^{-1} \), we have that:

\[
\lim_{n \to \infty} \left[ s_N \sum_{k \in E_n} \text{Cov}(Y_{0,n}^2, Y_{k,n}^2) - \frac{1}{\det(\Delta_0) | R_0 |} \int_{\mathbb{R}^d} f_0(x) \, dx \right] \\
\leq \lim_{n \to \infty} \left[ s_N \sum_{k \in E_n} \text{Cov}(Y_{0,n}^2, Y_{k,n}^2) - \frac{(s \lambda^{|n|})^d}{s N_n} \int_{\mathbb{R}^d} f_m(x) \, dx \right] \\
+ \lim_{n \to \infty} \left[ \frac{(s \lambda^{|n|})^d}{s N_n} \int_{\mathbb{R}^d} f_m(x) \, dx \right] - \frac{1}{\det(\Delta_0) | R_0 |} \int_{\mathbb{R}^d} f_0(x) \, dx \]

\[
\leq C \left( \epsilon_m + b(\epsilon_m)^d \right) + \frac{1}{\det(\Delta_0) | R_0 |} \int_{\mathbb{R}^d} f_m(x) \, dx - f_0(x) \, dx \to 0 \quad \text{as} \quad \epsilon_m \downarrow 0.
\]

Finally,

\[
\frac{1}{\det(\Delta_0) | R_0 |} \int_{\mathbb{R}^d} f_0(x) \, dx = \frac{2\pi^d}{| R_0 |} \int_{\mathbb{R}^d} \frac{| y + R_0 \cap R_0 |^2}{| R_0 |^2} \, dy.
\]

using a change of variables \( y = \Delta_0^{-1} x \). This completes the proof of Theorem 8.1. \( \square \)

For clarity of exposition, we will prove Theorem 3.1, parts (a) and (b), separately for the OL and NOL subsample variance estimators.

8.1 Proof of Theorem 3.1(a)

For \( i \in J_{OL} \), we use a Taylor’s expansion of \( H(\cdot) \) (around \( \mu \)) to rewrite the statistic \( \hat{\theta}_{k,n} = H(Z_{i,n}) \):

\[
\hat{\theta}_{k,n} = H(\mu) + \frac{\epsilon_n}{\| \epsilon_n \|} (Z_{i,n} - \mu)^a + 2 \frac{\epsilon_n}{\| \epsilon_n \|} \frac{(Z_{i,n} - \mu)^a}{a!} \int_{0}^{1} (1 - \omega) \frac{\omega^{a}}{a!} H(\mu + \omega (Z_{i,n} - \mu)) \, d\omega
\]

\[
\equiv H(\mu) + Y_{i,n} + Q_{i,n}. \quad (8.11)
\]

We also have: \( \hat{\theta}_n = H(\mu) + | J_{OL} |^{-1} \sum_{i \in J_{OL}} Y_{i,n} + | J_{OL} |^{-1} \sum_{i \in J_{OL}} Q_{i,n} \equiv H(\mu) + \bar{Y}_n + \bar{Q}_n \). Then,

\[
\tilde{\sigma}_{n,OL}^2 = s N_n \left[ \frac{1}{| J_{OL} |} \sum_{i \in J_{OL}} Y_{i,n}^2 \right] + \frac{2}{| J_{OL} |} \sum_{i \in J_{OL}} Q_{i,n}^2 + \frac{2}{| J_{OL} |} \sum_{i \in J_{OL}} Y_{i,n} Q_{i,n} - \bar{Y}_n^2 - \bar{Q}_n^2 - 2(\bar{Y}_n)(\bar{Q}_n).
\]

We establish Theorem 3.1(a) in two parts by showing

\[
(a) \quad \text{Var} \left( \frac{s N_n}{| J_{OL} |} \sum_{i \in J_{OL}} Y_{i,n}^2 \right) = K_0 \cdot \frac{\det(\Delta_n)}{\det(\Delta)} \cdot [2 \pi^d] (1 + o(1)),
\]

\[
(b) \quad \left| \text{Var} \left( \tilde{\sigma}_{n,OL}^2 \right) - \text{Var} \left( \frac{s N_n}{| J_{OL} |} \sum_{i \in J_{OL}} Y_{i,n}^2 \right) \right| = o \left( \frac{\det(\Delta_n)}{\det(\Delta)} \right).
\]

(8.12)

We will begin with proving (8.12)(a) above. For \( k \in \mathbb{Z}^d \), let \( \sigma_n(k) = \text{Cov}(Y_{0,n}^2, Y_{k,n}^2) \). We write

\[
\frac{s N_n}{| J_{OL} |^2} \text{Var} \left( \sum_{i \in J_{OL}} Y_{i,n}^2 \right) = \frac{(s N_n)^2}{| J_{OL} |^2} \left( \sum_{k \in E_n} J_n(k) \sigma_n(k) + \sum_{k \in \mathbb{Z}^d \setminus E_n} J_n(k) \sigma_n(k) \right) \equiv W_{1n} + W_{2n}.
\]
By stationarity and Lemma 8.2, we bound: $|\sigma_n(k)| \leq E(Y_{0,n}^2) \leq C(sN_n)^{-2}$, $k \in \mathbb{Z}^d$. Using this covariance bound, Lemmas 8.3-8.4, and $|E_n| \leq 3^d \det(\Delta_n)$:

$$
\left(\frac{sN_n}{|J_{ol}|}\right)^2 \sum_{k \in E_n} \sigma_n(k) - W_{1n} \right| \leq C \cdot \frac{|E_n|}{|J_{ol}|} \cdot \max_{k \in E_n} \left| 1 - \frac{J_n(k)}{|J_{ol}|} \right| = o\left(\frac{\det(s\Delta_n)}{\det(\Delta_n)}\right).
$$

(8.13)

Then applying Theorem 8.1 and Lemma 8.3,

$$
\left(\frac{sN_n}{|J_{ol}|}\right)^2 \sum_{k \in E_n} \sigma_n(k) = K_0 \cdot \frac{\det(s\Delta_n)}{\det(\Delta_n)} \cdot \left[2^{d-1}(1 + o(1))\right].
$$

(8.14)

By (8.13)-(8.14), we need only show that $W_{2n} = o\left(\frac{\det(s\Delta_n)}{\det(\Delta_n)}\right)$ to finish the proof of (8.12)(a).

For $i \in \mathbb{Z}^d$, denote a set of lattice points within a translated rectangular region:

$$
F_{ik} = \left(i + \prod_{j=1}^d \left(\lceil s\lambda_j^m \rceil / 2, \lceil s\lambda_j^m \rceil / 2\right)\right) \cap \mathbb{Z}^d,
$$

where $\lceil \cdot \rceil$ represents the “ceiling” function. Note that for $k = (k_1, \ldots, k_d)' \in \mathbb{Z}^d \setminus E_n$, there exists $j \in \{1, \ldots, d\}$ such that $|k_j| > s\lambda_j^m$, implying $\text{dis}(R_{0,n} \cap \mathbb{Z}^d, R_{k,n} \cap \mathbb{Z}^d) \geq \text{dis}(F_{0,n}, F_{k,n}) \geq 1$. Hence, sequentially using Lemmas 8.1-8.2, we may bound the covariances $\sigma_n(k), k \in \mathbb{Z}^d \setminus E_n$, with the mixing coefficient $\alpha(\cdot, \cdot)$:

$$
|\sigma_n(k)| \leq 8\left(E(\frac{2(2r+\delta)!}{r!})\right)^{2r/(2r+\delta)} \alpha(\text{dis}(\lambda_{0,n}, \mathbb{Z}^d, R_{k,n} \cap \mathbb{Z}^d), sN_n)^{d/(2r+\delta)} \leq C(sN_n)^{-2} \alpha(\text{dis}(F_{0,n}, F_{k,n}), sN_n)^{d/(2r+\delta)}.
$$

From the above bound and $J_n(k)/|J_{ol}| \leq 1$, $k \in \mathbb{Z}^d$, we have

$$
|W_{2n}| \leq C|J_{ol}|^{-1} \sum_{x \in \mathbb{Z}^d} \left(\sum_{j=1}^d C(x,j,n)\right) \alpha(x, sN_n)^{d/(2r+\delta)},
$$

(8.15)

$$
C_{(x,j,n)} = \left\{ i \in \mathbb{Z}^d : \text{dis}(F_{0,n}, F_{k,n}) = x = \inf \{|v_j - w_j| : v \in F_{0,n}, w \in F_{k,n}\}\right\}.
$$

The function $C_{(x,j,n)}$ counts the number of translated rectangles $F_{ik}$ that lie a distance of $x \in \mathbb{Z}_+$ from the rectangle $F_{0,n}$, where this distance is realized in the $j$th coordinate direction for $j = 1, \ldots, d$. For $i \in \mathbb{Z}^d$, $x \geq 1$ and $j \in \{1, \ldots, d\}$, if $\text{dis}(F_{0,n}, F_{k,n}) = x = \inf \{|v_j - w_j| : v \in F_{0,n}, w \in F_{k,n}\}$, then $|v_j| = |s\lambda_j^m| + x - 1$ with the remaining components of $i$, namely $i_m$ for $m \in \{1, \ldots, d\} \setminus \{j\}$, constrained by $|i_m| \leq s\lambda_m^m + x$. We use this observation to further bound the right hand side of (8.15) by:

$$
C|J_{ol}|^{-1} \sum_{x=1}^\infty \left(\sum_{j=1}^d \prod_{m=1, j \neq m}^d 3(s\lambda_m^m + x)\right) \alpha(x, sN_n)^{d/(2r+\delta)}
$$

$$
\leq C \cdot \frac{\det(s\Delta_n)}{|J_{ol}|} \sum_{j=1}^d \left(\sum_{x=1}^{s\lambda_j^m + 1} x^{-j} + \sum_{x=s\lambda_j^m + 1}^\infty x^{-1} [\alpha_1(x) g(s\lambda_j^m)]^{d/(2r+\delta)}\right)
$$

$$
\leq C \cdot \frac{\det(s\Delta_n)}{|J_{ol}|} \sum_{j=1}^d \left(\sum_{x=1}^{s\lambda_j^m + 1} x^{-j} + \sum_{x=s\lambda_j^m + 1}^\infty x^{-1} [\alpha_1(x) g(s\lambda_j^m)]^{d/(2r+\delta)}\right)
$$

$$
\leq C \cdot \frac{\det(s\Delta_n)}{|J_{ol}|} \sum_{j=1}^d \left(\sum_{x=1}^{s\lambda_j^m + 1} x^{-j} + \sum_{x=s\lambda_j^m + 1}^\infty x^{-1} [\alpha_1(x) g(s\lambda_j^m)]^{d/(2r+\delta)}\right)
$$

using Assumptions A.1, A.3, Condition $M_r$, and $\ell_n = o(s\lambda_m^m)$. This completes the proof of (8.12)(a).

To establish (8.12)(b), first note that

$$
\left|\text{Var}(\hat{r}_{n,ol}^2) - \text{Var}\left(\frac{sN_n}{|J_{ol}|} \sum_{i \in J_{ol}} Y_i^2\right)\right| \leq 4 \left(\sum_{j=1}^5 \frac{A_j^{1/2}}{|J_{ol}|}\right) \left(\sum_{j=1}^5 \frac{A_j^{1/2}}{|J_{ol}|} + \text{Var}^{1/2}\left(\frac{sN_n}{|J_{ol}|} \sum_{i \in J_{ol}} Y_i^2\right)\right).
$$

23
where $A_{1n} = \text{Var}(s_{N,n} Y^2_{k,n})$, $A_{2n} = \text{Var}([J_{i,n}]^{-1} s_{i,n} \sum_{i \in J_{i,n}} Q^2_{i,n})$, $A_{3n} = \text{Var}(s_{N,n} \tilde{Q}_{k,n})$, $A_{4n} = \text{Var}([J_{i,n}]^{-1} s_{i,n} \sum_{i \in J_{i,n}} Y_{i,n} \tilde{Q}_{k,n})$, $A_{5n} = \text{Var}(s_{N,n} \tilde{Y}_{i,n})$.

By (8.12)(a), it suffices to show that $A_{jn} = o(\text{det}(s_{N,n})/\text{det}(\Delta_n))$ for each $j = 1, \ldots, 5$. We handle only two terms for illustration: $A_{1n}, A_{2n}$.

Consider $A_{1n}$. For $s \in R_n \cap Z^d$, let $\omega(s) = \{2^d \text{det}(s_{N,n}) \}^{-1/2} [i \in J_{i,n} : s \in i + \Delta_n R_n]\}$ so that $0 \leq \omega(s) \leq 1$. By Condition $M_r$ and Theorem 3, Doukhan (1994, p.31) (similar to Lemma 8.2),

$$A_{1n} \leq E[\hat{Y}_{i,n}^4] \leq \left(\frac{2^d \text{det}(s_{N,n})}{|J_{i,n}|} \right)^4 \frac{\left(\sum_{s \in R_n \cap Z^d} \omega(s) \nabla^2 (Z(s) - \mu)\right)^4}{|J_{i,n}|^4 (s_{N,n})^4} \leq C \cdot \left(\frac{s_{N,n}^2 (\text{det}(s_{N,n})^{2}}{|J_{i,n}|^4 (s_{N,n})^4}\right).$$

Then $A_{1n} = o(\text{det}(s_{N,n})/\text{det}(\Delta_n))$ follows from Lemma 8.3.

To handle $A_{2n}$, write $\sigma_{1n}(k) = \text{Cov}(Y_{0,n} Q_{0,n}, Y_{k,n} Q_{k,n})$, $k \in \mathbb{Z}^d$. Then,

$$A_{2n} = \left(\frac{s_{N,n}}{|J_{i,n}|^2} \right)^2 \sum_{k \in \mathbb{Z}^d} J_n(k) \sigma_{1n}(k) \leq \left(\frac{s_{N,n}}{|J_{i,n}|^2} \right)^2 \left(\sum_{k \in E_n} \sigma_{1n}(k) + \sum_{k \in \mathbb{Z}^d \setminus E_n} \sigma_{1n}(k)\right) = A_{1n}(E_n) + A_{2n}(E_n^c).$$

For $k \in E_n$, note $|\sigma_{1n}(k)| \leq C \cdot s_{N,n}^{-2} \text{dist}(F_{0,n} \cap \mathbb{Z}^d, F_{k,n} \cap \mathbb{Z}^d)$ (from Condition $D$) with Lemmas 8.1-8.2. From this bound, Lemma 8.3, and $|E_n| \leq 3^d \text{det}(s_{N,n})$, we find $A_{1n}(E_n) = o(\text{det}(s_{N,n})/\text{det}(\Delta_n))$. We next bound the covariances $\sigma_{1n}(k)$, $k \in \mathbb{Z}^d \setminus E_n$,

$$|\sigma_{1n}(k)| \leq C \cdot s_{N,n}^{-2} \text{dist}(F_{0,n} \cap \mathbb{Z}^d, F_{k,n} \cap \mathbb{Z}^d), s_{N,n}^{\delta/2},$$

by the stationarity of the random field $Z(.)$ and Lemmas 8.1-8.2. Using this inequality and repeating the same steps used to majorize ‘$W_{2n}$’ from the proof of (8.12)(a) (see (8.15)), we have $A_{2n}(E_n^c) = o(\text{det}(s_{N,n})/\text{det}(\Delta_n))$. The proof of Theorem 3.1(a) is finished. □

8.2 Proof of Theorem 3.1(b)

To simplify the counting arguments, we assume here that $s_{\Delta,n} \in \mathbb{Z}_+$, implying $s_{N,n} = s_{i,n}$, $i \in \mathbb{Z}^d$. The more general case, in which the NOL subregions may differ in the number of sampling sites, is treated in Nordman (2002).

For each NOL subregion $\hat{R}_{k,n}$, we denote the corresponding sample mean $\hat{Z}_{k,n} = (s_{N,n})^{-1} \sum_{s \in \hat{R}_{k,n} \cap \mathbb{Z}^d} Z(s)$.

The subsample evaluations of the statistic of interest, $\theta_{k,n} = (s_{N,n})^{-1} \sum_{i \in J_{NOL} \cap \mathbb{Z}^d} Z(s)$, can be expressed through a Taylor’s expansion of $H(.)$ around $\mu$, substituting $\tilde{Z}_{k,n}$ for $Z_{k,n}$ in (8.11): $\tilde{\theta}_{k,n} = H(\tilde{Z}_{k,n}) = H(\mu) + \tilde{Y}_{k,n} + \tilde{Q}_{k,n}$.

We will complete the proof of Theorem 3.1(b) in two parts by showing

$$\var\left(\frac{s_{N,n}}{|J_{NOL}|} \sum_{i \in J_{NOL}} \tilde{Y}_{i,n}^2 \right) = \frac{\text{det}(\Delta_n)}{\text{det}(\Delta_n)^2} \left[2^d(1 + o(1))\right], \quad \text{Var}\left(\frac{s_{N,n}}{|J_{NOL}|} \sum_{i \in J_{NOL}} \tilde{Y}_{i,n}^2 \right) = o\left(\frac{\text{det}(\Delta_n)}{\text{det}(\Delta_n)^2}\right).$$

We will begin with showing (8.17)(a). For $k \in \mathbb{Z}^d$, let $\tilde{J}_n(k) = \{i \in J_{NOL} : i + k \in J_{NOL}\}$ and $\tilde{\sigma}_n(k) = \text{Cov}(\tilde{Y}_{i,n}, \tilde{Y}_{k,n})$. Then we may express the variance:

$$\text{Var}\left(\frac{s_{N,n}}{|J_{NOL}|} \sum_{i \in J_{NOL}} \tilde{Y}_{i,n}^2 \right) = \left(\frac{s_{N,n}}{|J_{NOL}|^2} \right)^2 \left(\sum_{k \in \mathbb{Z}^d} \tilde{J}_n(k) \tilde{\sigma}_n(k) + \sum_{k \in \mathbb{Z}^d} \tilde{J}_n(k) \tilde{\sigma}_n(k) + |J_{NOL}| \tilde{\sigma}_n(0)\right) \equiv U_{1n} + U_{2n} + |J_{NOL}|^{-1} s_{N,n}^{-2} \tilde{\sigma}_n(0).$$

We first prove $U_{2n} = o(|J_{NOL}|^{-1})$, noting that $\text{det}(s_{N,n})/\text{det}(\Delta_n) = O(|J_{NOL}|^{-1})$ from Lemma 8.3.
When \( \mathbf{k} = (k_1, \ldots, k_d)^t \in \mathbb{Z}^d, \|\mathbf{k}\|_\infty > 1 \), then for some \( 1 \leq m_k \leq d \):

\[
\text{dis}(\hat{R}_{0,n} \cap \mathbb{Z}^d, \hat{R}_{k,n} \cap \mathbb{Z}^d) \geq \text{dis}\left(\triangle_n[-1/2, 1/2]^d, \hat{\triangle}_n(\mathbf{k} + [-1/2, 1/2]^d)\right) = \max_{1 \leq j \leq d} |\{k_j\} - 1| \cdot \lambda_j^{\alpha}\left|\{k_j\} - 1\right| \cdot \lambda_j^{\alpha}.
\]

If \( j \in \{1, \ldots, d\}, j \neq m_k \), we have \( |\{k_j\} - 1| \cdot \lambda_j^{\alpha}\left|\{k_j\} - 1\right| \cdot \lambda_j^{\alpha} + 1 \). Note also if \( \mathbf{k} \in \mathbb{Z}^d, \|\mathbf{k}\|_\infty > 1 \), then

\[
[\hat{\sigma}(\mathbf{k})] \leq C(\mathbf{s} N_n)^{-1} \alpha \left(\{\hat{\lambda}_{m_k}^{\alpha}\} - 1\right) \cdot \lambda_{m_k}^{\alpha}.
\]

We have

\[
|U_{2n}| \leq \frac{C}{|J_{so}|} \sum_{x = 1}^{\infty} \left(\sum_{j = 1}^{d} \left(\lambda_j^{\alpha}\left|\{x_j\} - 1\right| \cdot \lambda_j^{\alpha} + x_j\right)\right) \cdot \alpha \left(\{s N_n\} - 1\right) \cdot \lambda_{m_k}^{\alpha} = o\left(1\right),
\]

by Assumptions A.1, A.3 and Condition \( M_r \).

We now show that \( U_1 = o(1) \). For \( \mathbf{k} \in \mathbb{Z}^d, 0 < \|\mathbf{k}\|_\infty \leq 1 \), define the trimmed set:

\[
T_{k,n}^j = \begin{cases} 
\{x \in \mathbb{R}^d : 1/2 \cdot \lambda_j^{\alpha} < x_j \leq 1/2 \cdot \lambda_j^{\alpha} + \ell_n\} & \text{if } k_j = 1, \\
\{x \in \mathbb{R}^d : -1/2 \cdot \lambda_j^{\alpha} \leq x_j \leq -1/2 \cdot \lambda_j^{\alpha}\} & \text{if } k_j = -1, \\
\emptyset & \text{if } k_j = 0.
\end{cases}
\]

for each coordinate direction \( j = 1, \ldots, d \). Let \( T_{k,n} = \bigcup_{j = 1}^{d} T_{k,n}^j \). We decompose the sum: \( s N_n \hat{Y}_{k,n} = \sum(\hat{R}_{k,n} \setminus T_{k,n}) + \sum(\hat{R}_{k,n} \cap T_{k,n}) \equiv \hat{S}_{k,n} + \hat{S}_{k,n}^* \). Then, \( U_1 = o\left(1\right) \) follows from (1)-(4) below:

1. \( |E(\hat{Y}_{0,n}^2 \hat{S}_{k,n} \hat{S}_{k,n}^*)| \leq |E(\hat{Y}_{0,n}^4)E(\hat{S}_{k,n}^3)E(\hat{S}_{k,n}^*3)|^{1/3} = o(1) \), using Lemma 8.2 and

\[
|\hat{R}_{k,n} \cap T_{k,n} \cap \mathbb{Z}^d| \leq \sum_{j = 1}^{d} |\hat{R}_{k,n} \cap T_{k,n}^j \cap \mathbb{Z}^d| \leq \ell_n \text{det}(\hat{s}_n) \sum_{j = 1}^{d} (\lambda_j^{\alpha})^{-1}.
\]

2. Likewise, \( E(\hat{Y}_{0,n}^2 \hat{S}_{k,n}^3) \leq E(\hat{Y}_{0,n}^4)E(\hat{S}_{k,n}^3)^{1/2} = o(1) \).

3. \( |N_n E(\hat{Y}_{0,n}^2) - (\sum_n)^{-1} E(\hat{S}_{k,n}^2)| \leq 4(\sum_n)^{-1} \max \left\{ E(\hat{S}_{k,n}^2)E(\hat{S}_{k,n}^2)^{1/2}, E(\hat{S}_{k,n}^2)\right\} = o(1) \).

4. \( |\text{Cov}(\hat{Y}_{0,n}^2, \hat{S}_{k,n}^3)| \leq \alpha(\ell_n s_n^{3/2} + \ell_n^{3/2}) = o(1) \) by applying Lemmas 8.1-8.2, Assumption A.3, and Condition \( M_r \) with \( \text{dis}(\hat{R}_{k,n} \cap \mathbb{Z}^d \setminus T_{k,n}, s R_n \cap \mathbb{Z}^d) \geq \ell_n \).

Since \( \hat{\sigma}_n(0) = \sqrt{\mathbb{V}(\hat{Y}_{0,n}^2)}, \) the remaining quantity in (8.18) can be expressed as

\[
\frac{(\sum_n)^2}{|J_{so}|} \cdot \hat{\sigma}_n(0) = \frac{1}{|J_{so}|} \cdot \text{Var}\left(\mathbb{V}(\hat{Y}_{0,n}^2)^2\right)(1 + o(1)) = \frac{\text{det}(\hat{s}_n)}{\text{det}(\hat{s}_n)|R_0|}[2\pi^4](1 + o(1))
\]

by applying the CLT (as in (8.8)) and Lemma 8.3. We have now established (8.17) \((a)\).

We omit the proof of (8.17) \((b)\), which resembles the one establishing (8.12) \((b)\) and incorporates arguments used to bound \( U_{1n}, U_{2n} \); Nordman (2002) provides more details. \(\square\)

## 9 Proofs for bias expansions

We will use the following lemma concerning \( \hat{\sigma}_n^2 = N_n \cdot \text{Var}(\hat{\sigma}_n) \) to prove the theorems pertaining to bias expansions of \( \hat{\sigma}_{n,ol}^2 \) and \( \hat{\sigma}_{n,nonol}^2 \).
Lemma 9.1 Under the Assumptions and Conditions of Theorem 3.1,

$$\tau_n^2 = \tau^2 + O\left(\left[\det(\Delta_n)\right]^{-1/2}\right).$$

Proof: By a Taylor’s expansion around $\mu$, $\hat{\theta}_n = H(\hat{Z}_n) = H(\mu) + \hat{Z}_n - \hat{Q}_n$, (replacing $\hat{Z}_n$ for $Z_n$ in (8.11)) and so $N_n\text{Var}(\hat{\theta}_n) = N_n\text{Var}(\hat{Y}_n + Q_n)$. For $k \in \mathbb{Z}^d$, let $N_n(k) = |\{i \in R_n \cap \mathbb{Z}^d : i + k \in R_n\}|$. It holds that $N_n(k) \leq N_n$ and

$$N_n \leq N_n(k) + |\{i \in \mathbb{Z}^d : T^i \cap R_n \neq \emptyset, T^i \cap R_n^c \neq \emptyset; T^i = i + \|k\|_\infty [-1, 1]^d\}| \leq N_n(k) + C\|k\|_\infty^{d(\lambda^{max}_n - 1)}. \tag{9.1}$$

by the boundary condition on $R_0$. Also, by Lemma 8.1 and stationarity, for each $k \neq 0 \in \mathbb{Z}^d$,

$$|\sigma(k)| \leq C_\alpha_1(\|k\|_\infty)^{\delta/(2\alpha + \delta)}, \quad k \in \mathbb{Z}^d. \tag{9.2}$$

Using $|\{k \in \mathbb{Z}^d : \|k\|_\infty = x\}| \leq Cx^{d-1}$, $x \geq 1$, the covariances are absolutely summable over $\mathbb{Z}^d$:

$$\sum_{k \in \mathbb{Z}^d} |\sigma(k)| \leq |\sigma(0)| + C \sum_{x=1}^\infty x^{d-1} \alpha_1(x)^{\delta/(2\alpha + \delta)} < \infty. \tag{9.3}$$

From (9.1)-(9.3), we find

$$N_n\text{Var}(\hat{Y}_n) = \frac{1}{N_n} \sum_{k \in \mathbb{Z}^d} N_n(k) \sigma(k) = \tau^2 + I_n; \tag{9.4}$$

$$|I_n| \leq \frac{1}{N_n} \sum_{k \in \mathbb{Z}^d} |N_n - N_n(k)| \cdot |\sigma(k)| \leq C \cdot \left(\frac{\lambda^{max}_n}{N_n}\right)^{d-1} \sum_{x=1}^\infty x^{2d-1} \alpha_1(x)^{\delta/(2\alpha + \delta)} = O\left(\left[\det(\Delta_n)\right]^{-1/d}\right). \tag{9.5}$$

By Condition D and Lemma 8.2, it follows that $N_n\text{Var}(\hat{Q}_n) = O\left(\left[\det(\Delta_n)\right]^{-1}\right)$.

Finally, with bounds on the variance of $\hat{Y}_n$ and $\hat{Q}_n$, we apply the Cauchy-Schwarz inequality to the covariance: $N_n\text{Cov}(\hat{Y}_n, \hat{Q}_n) = O\left(\left[\det(\Delta_n)\right]^{-1/2}\right)$, setting the order on the difference $|N_n\text{Var}(\hat{\theta}_n) - \tau^2|$.

We give a few lemmas which help compute the bias of the estimators $\tau_{n,ol}^2$ and $\tau_{n,n,ol}^2$.

Lemma 9.2 Let $\bar{Y}_i = (s_{V,n})^{-1} \sum_{s \in Z^d} (\hat{Y}_n(s) - \mu), i \in \mathbb{Z}^d$. Suppose Assumptions A.1 - A.5 and Conditions D.2 and M_{2+a} hold with $d \geq 2$. Then,

$$\mathbb{E}(\tau_{n,ol}^2) = s_N(\mathbb{E}(\bar{Y}_n^2) + \mathbb{E}(\hat{Q}_n^2) + 2\mathbb{E}(\hat{Y}_n Q_0,n) - \mathbb{E}(\bar{Y}_n^2) - \mathbb{E}(\hat{Y}_n) - \mathbb{E}(\hat{Q}_n)). \tag{9.6}$$

Proof: We consider here only $\mathbb{E}(\tau_{n,ol}^2)$. For integer $\Delta_n$, the arguments for $\mathbb{E}(\tau_{n,n,ol}^2)$ are essentially the same; more details are provided in Nordman (2002).

By stationarity and an algebraic expansion:

$$\mathbb{E}(\tau_{n,ol}^2) = s_N E(Y_0^2) + s_N E(Q_0^2) + 2E(Y_0 Q_0,n) - E(Y_0^2) - E(Y_0) - E(Q_0).$$

With the moment arguments based on Lemma 8.2 and Condition D_r, we have

$$s_N E(Y_0^2) \leq C, \quad s_N E(Y_0^2) \leq C s_N(N_n)^{-1}, \quad s_N E(Q_0^2) \leq C s_N(N_n)^{-1}, \tag{9.6}$$

26
where bound on $sN_n E(\hat{Y}_n^2)$ follows from (8.16). By Holder’s inequality and Assumption A.2:

$$E(\tilde{\tau}_{n,\text{ol}}^2) = sN_n E(Y_0^2) + O\left(sN_n^{-1/2}\right) + O\left(sN_n (N_n)^{-1}\right).$$

Note that $E(Y_0^2) = E(\hat{Y}_0^2)$. $sN_n = sN_0$. Hence, applying Lemma 8.3 and Assumption A.2, we establish Lemma 9.2 for $\tilde{\tau}_{n,\text{ol}}^2$. □

The next lemma provides a small refinement to Lemma 9.2 made possible when the function $H(\cdot)$ is smoother. We shall make use of this lemma in bias expansions of $\tilde{\tau}_{n,\text{ol}}^2$ and $\tilde{\tau}_{n,\text{ol}}^2$ in lower sampling dimensions, namely $d = 1$ or 2.

**Lemma 9.3** Assume $d = 1$ or 2. In addition to Assumptions A.1 - A.5, suppose that Conditions D.2 and $M_3+\alpha$ hold. Then,

$$E(\tilde{\tau}_{n,\text{ol}}^2) - \frac{1}{sN_0} E(Y_0^2) = \begin{cases} O\left|\det(s\Delta_n)\right|^{-1} & \text{if } d = 1, \\ O\left(\left|\det(s\Delta_n)\right|^{-1/2}\right) & \text{if } d = 2. \end{cases}$$

**Proof:** We again consider only $\tilde{\tau}_{n,\text{ol}}^2$. For $i \in J_{\text{ol}}$, we use a third-order Taylor’s expansion of each subsample statistic around $\mu$: $\tilde{\theta}_n = H(\mu) + Y_i + Q_i + C_i$, where $Y_i = \nabla'(Z_i - \mu)$.

$$Q_i = \sum_{||\omega||_2 < 2} c_0^\omega (Z_i - \mu)^\omega, \quad C_i = 3 \sum_{||\omega||_0 < 3} c_0^\omega (Z_i - \mu)^\omega \int_0^1 (1 - \omega_2^2 D^\omega H(\mu + \omega(Z_i - \mu)) d\omega.$$ Here $C_i$ denotes the remainder term in the Taylor’s expansion and $Q_i$ is defined a little differently. Write the sample means for the Taylor terms: $\tilde{Y}_i, \bar{Q}_i$ as before, $C_i = |J_{\text{ol}}|^{-1} \sum_{i \in J_{\text{ol}}} C_i$. The moment inequalities in (9.6) are still valid and, by Lemma 8.2 and Condition D, we can produce bounds: $sN_n E(C_i^2) = sN_n E(C_i^2) \leq C(sN_n)^{-2}$. By Holder’s inequality and the scaling conditions from Assumptions A.1-A.2, we then have

$$E(\tilde{\tau}_{n,\text{ol}}^2) = sN_n \left[E(\tilde{Y}_0^2) + 2E(Y_0, \bar{Q}_0) \right] + \begin{cases} O\left|\det(s\Delta_n)\right|^{-1} & \text{if } d = 1, \\ O\left(\left|\det(s\Delta_n)\right|^{-1/2}\right) & \text{if } d = 2. \end{cases}$$

Since $sN_n E(Y_0^2) = sN_0 E(\hat{Y}_0^2)$, Lemma 9.3 for $\tilde{\tau}_{n,\text{ol}}^2$ will follow by showing

$$sN_n E(Y_0, \bar{Q}_0) = sN_n \sum_{i,j,k=1}^p c_i a_{j,k} \mathbb{E}\left\{ (Z_{i,0,n} - \mu)(Z_{j,0,n} - \mu)(Z_{k,0,n} - \mu) \right\} = O\left(\left|\det(s\Delta_n)\right|^{-1}\right).$$

(9.7)

where $Z_0 = (Z_{1,0,n}, \ldots, Z_{p,0,n}) \in \mathbb{R}^p$ is a vector of coordinate sample means; $c_i = \partial H(\mu)/\partial x_i; a_{j,k} = 1/2 \cdot \partial^2 H(\mu)/\partial x_j \partial x_k$.

Denote the observation $Z(s) = (Z_1(s), \ldots, Z_p(s)) \in \mathbb{R}^d, \ s \in \mathbb{Z}^d$. Fix $i, j, k \in \{1, \ldots, p\}$ and WLOG assume $\mu = 0$. Then $sN_n \mathbb{E}\{Z_i(s) Z_j(s) Z_k(s)\} = |sN_n|^{-1} \mathbb{E}\{Z_i(t) Z_j(t) Z_k(t)\} + L_{1n} + L_{2n}^j$ where

$$L_{1n}^{ijk} = \frac{\left(sN_n\right)^{-2}}{\sum_{u,v,w \in \mathbb{Z}^d, n \neq n_u \neq n_v \neq n_w} \mathbb{E}\left\{ Z_i(u) Z_j(v) Z_k(w) \right\},$$

$$L_{2n}^{ij} = \frac{\left(sN_n\right)^{-2}}{\sum_{u \in \mathbb{Z}^d, n \neq n_u} \mathbb{E}\left\{ Z_i(u) Z_j(u) Z_k(v) + Z_i(u) Z_j(v) Z_k(u) + Z_i(v) Z_j(u) Z_k(u) \right\}.$$ By Lemma 8.1, Assumption A.3, and Condition $M_r$,

$$|L_{2n}^{ijk}| \leq \frac{C}{sN_n} \sum_{x=1}^{\infty} x^{d-1} \alpha(x, 1)^{(2r+d)} = O\left(\left|\det(s\Delta_n)\right|^{-1}\right).$$
similar to (9.3). For \(y_1, y_2, y_3 \in \mathbb{R}^d\), define \(\text{dis}_3(\{y_1, y_2, y_3\}) = \max_{1 \leq i < j \leq 3} \text{dis}(\{y_i, \{y_1, y_2, y_3\}\})\). If \(x \geq 1 \in \mathbb{Z}_+\), then \(\{(y_1, y_2) \in (\mathbb{Z}^d)^2 : \text{dis}_3(\{y_1, y_2, 0\}) = x\} \leq Cx^{2d-1}\) from Theorem 4.1, Lahiri (1999a). Thus,

\[
|L_{i,n}^{j,k}| \leq \frac{C}{sN_n} \sum_{x=1}^{\infty} x^{2d-1} \alpha(x, 2)^{\delta/(2r+\delta)} = O\left(\left|\det(s\Delta_n)\right|^{-1}\right).
\]

This establishes (9.7), completing the proof of Lemma 9.3 for \(s_n^{2,n,\text{OL}}\). \(\square\)

We use the next lemma in the proof of Theorem 4.2. It allows us to approximate lattice point counts with Lebesgue volumes, in \(\mathbb{R}^d\) or \(\mathbb{R}^3\), to a sufficient degree of accuracy.

**Lemma 9.4** Let \(d = 2, 3\) and \(R_0 \subseteq (-1/2, 1/2]^d\) such that \(B^c \subseteq R_0 \subseteq \overline{B}\) for a convex set \(B\). Let \(\{b_n\}_{n=1}^\infty\) be a sequence of positive real numbers such that \(b_n \to \infty\). If \(k \in \mathbb{Z}^d\), then there exists \(N_k \in \mathbb{Z}_+\) and \(C_d > 0\) such that for \(n \geq N_k\), \(i \in \mathbb{Z}^d\),

\[
\left|\left\{b_nR_0 - \mathbb{Z}^d \cap b_n(i + R_0)\right\} - \left\{b_nR_0 \cap k + b_nR_0 - \mathbb{Z}^d \cap b_n(i + R_0) \cap k + b_n(i + R_0)\right\}\right| \leq C_d \|k\|_\infty^2 \left(\left\|b_n^2\right\|_\infty + \xi_{k,n} b_n^2\right) \quad \text{if } d = 2,
\]

\[
\left\{C_3 \|k\|_\infty^4 \right. \left(\left\|b_n^2\right\|_\infty^2 + \xi_{k,n} b_n^2\right) \quad \text{if } d = 3,
\]

where \(\{\xi_{k,n}\}_{n=1}^\infty \subset \mathbb{R}\) is a nonnegative sequence (possibly dependent on \(k\)) such that \(\xi_{k,n} \to 0\).

**Proof:** Provided in Nordman and Lahiri (2002). \(\square\)

To establish Lemma 4.1, we require some additional notation. For \(i, k \in \mathbb{Z}^d\), let \(sN_{i,n}(k) = \mathbb{Z}^d \cap \tilde{R}_{i,n} \cap k + \tilde{R}_{i,n}\) denote the number of sampling sites (lattice points) in the intersection of a NOL subregion with its \(k\)-translate. Note \(sN_{i,n}(k)\) is a subsample version of \(N_{i,n}(k)\) from (9.1).

**Proof of Lemma 4.1:** We start with bounds:

\[
\sup_{i \in \mathbb{Z}^d} \left|sN_i - sN_{i,n}\right| \leq C_d \left(s_{\Delta_n}^{\text{max}}\right)^{d-1},
\]

(9.8)

\[
\left|sN_{i,n} - sN_{i,n}(k)\right| \leq \left|\left\{j \in \mathbb{Z}^d : T_j \cap \tilde{R}_{i,n} \neq \emptyset, T_j \cap \tilde{R}_{i,n} \neq \emptyset, T_j = j + k \end{aligned}\right\|_\infty \left(\left\|b_n^2\right\|_\infty + \xi_{k,n} b_n^2\right) \quad \text{if } d = 2,
\]

\[
\left\{C_3 \|k\|_\infty^4 \right. \left(\left\|b_n^2\right\|_\infty^2 + \xi_{k,n} b_n^2\right) \quad \text{if } d = 3,
\]

(9.9)

by the boundary condition on \(R_0\) (cf. Lemma 8.3) and \(\inf_{j \in \mathbb{Z}^d} \|s\Delta_n j - j\|_\infty \leq 1/2\).

Modify (9.4) by replacing \(N_n, N_{i,n}(k)\) with \(sN_{i,n}, sN_{i,n}(k)\), \(\tilde{Y}_{i,n} = \nabla' (\tilde{Z}_{i,n} - \mu)\) (i.e., use a NOL subsample version in place of the sample one); and replace \(N_n, \Delta_n, \lambda_{\Delta_n}^{\text{max}}\) with the subsample analogs \(sN_{i,n}, \Delta_{i,n}, s\lambda_{\Delta_n}^{\text{max}}\) in (9.5). We then find using (9.3): for each \(i \in \mathbb{Z}^d\),

\[
sN_{i,n}E(\tilde{Y}_{i,n}^2) - \tau^2 = \frac{1}{sN_{i,n}} \sum_{k \in \mathbb{Z}^d} (sN_{i,n}(k) - sN_{i,n}) \tau(k) \equiv sJ_{i,n},
\]

(10.9)

\[
\sup_{i \in \mathbb{Z}^d} \left|sJ_{i,n}\right| \leq \sup_{i \in \mathbb{Z}^d} \left\{\frac{1}{sN_{i,n}} \sum_{k \in \mathbb{Z}^d} \left|sN_{i,n}(k) - sN_{i,n}\right| \tau(k)\right\}\]

\[
\leq C \cdot \frac{\left(s\lambda_{\Delta_n}^{\text{max}}\right)^{d-1}}{sN_{i,n} - C_d \left(s\lambda_{\Delta_n}^{\text{max}}\right)^{d-1}} \sum_{x=1}^{\infty} x^{2d-1} \alpha(x, 2)^{\delta/(2r+\delta)} = O\left(\left|\det(s\Delta_n)\right|^{-1/d}\right),
\]

(11.11)

from (9.8)-(9.9) and Assumption A.1. Now applying Lemma 9.1 and Assumption A.2 with Lemma 9.2 for \(d \geq 2\) or Lemma 9.3 for \(d = 1\), Lemma 4.1 follows. \(\square\)
Proof of Theorem 4.1: Here \( s N_{i,n} = s N_{i}, s N_{i,k}(k) = C_{n}(k), E(\tilde{Y}_{i,n}) = E(\tilde{Y}_{i,n}) \) for each \( i, k \in \mathbb{Z}^d \) (since \( s \lambda_{n} \in \mathbb{Z}_{+} \)) and \( \det(\Delta_{n}) = \lambda_{n}^{d}. \) Applying Lemma 9.2 for \( d \geq 3 \) and Lemma 9.3 for \( d = 2, \) Lemma 9.1, Assumption A.2, and (9.11):

\[
E\left( \tau_{n}^{2} - \tau_{n}^{2} \right) = \frac{-1}{s \lambda_{n}[R_{0}]} \sum_{k \in \mathbb{Z}^d} g_{n}(k) + o(s \lambda_{n}^{-1}), \quad g_{n}(k) \equiv \frac{s N_{i,n} - C_{n}(k)}{s \lambda_{n}^{d-1}} \cdot \sigma(k).
\]

From (9.11) and Lemma 8.3, it follows that \( \sum_{k \in \mathbb{Z}^d} |g_{n}(k)| \leq \mathcal{C}, \quad n \in \mathbb{Z}_{+} \) and that \( g_{n}(k) \to C(k) \sigma(k) \) for \( k \in \mathbb{Z}^d. \) By the LDCT, the proof of Theorem 4.1 is complete. \( \square \)

To establish Theorem 4.2, we require some additional notation. For \( i, k \in \mathbb{Z}^d, \) denote the difference between two Lebesgue volume-for-lattice-point-count approximations as:

\[
D_{i,n}(k) = \left( |R_{i,n}| - s N_{i,n} \right) - \left( |R_{i,n} \cap k + R_{i,n}| - s N_{i,n}(k) \right) - \left( |R_{i,n}| - s N_{i,n} \right) - \left( |R_{i,n} \cap k + R_{i,n}| - s N_{i,n}(k) \right).
\]

Proof of Theorem 4.2: We handle here the cases \( d = 2 \) or \( 3. \) Details on the proof for \( d = 1 \) are given in Nordman (2002). We note first that if \( V(k) \) exists for each \( k \in \mathbb{Z}^d, \) then Lemma 9.4 implies \( C(k) = V(k). \)

Consider \( \tau_{n,o,l}^{2}. \) Applying Lemma 9.2 for \( d = 3, \) and Lemma 9.3 for \( d = 2, \) with (9.8), (9.10), and (9.11) gives

\[
E\left( \tau_{n,o,l}^{2} \right) - \tau_{n,o,l}^{2} = |J_{n,o}|^{-1} \sum_{i \in J_{n,o}} \frac{s N_{i,n}}{|R_{i}|} I_{i,n} + o(s \lambda_{n}^{-1}).
\]

Then, using (9.3), we can arrange terms to write

\[
|J_{n,o}|^{-1} \sum_{i \in J_{n,o}} \frac{s N_{i,n}}{|R_{i}|} I_{i,n} = \Psi_{n} + \sum_{k \in \mathbb{Z}^d} \frac{G_{n}(k)}{s \lambda_{n}^{d-1}} |R_{0}|; \quad G_{n}(k) = \sum_{i \in J_{n,o}} \frac{D_{i,n}(k) \cdot \sigma(k)}{s \lambda_{n}^{d-1}} |J_{n,o}|,
\]

for \( \Psi_{n} = -\sum_{k \in \mathbb{Z}^d} \frac{|R_{i}|^{-1}}{|i|} \left( |s R_{i}| - |s R_{i} \cap k + s R_{i}| \right) \sigma(k). \) Since \( R_{0} \) is convex, the boundary condition is valid and it holds that for all \( i, k \in \mathbb{Z}^d:

\[
\left| s N_{i,n}(k) - |s R_{i} \cap k \cap R_{0}| \right| \leq \mathcal{C}(s \lambda_{n}^{d-1}) \quad \text{and} \quad \left| s N_{i,n}(k) - |s R_{i} \cap k + s R_{i}| \right| \leq \mathcal{C} \quad \left| k \right|^{d} (s \lambda_{n}^{d})^{d-1} \quad (9.12)
\]

from Lemma 8.3 and (9.9). Then (9.3), Lemma 9.4, and (9.12) give: \( \sum_{k \in \mathbb{Z}^d} |G_{n}(k)| \leq \mathcal{C}, \quad n \in \mathbb{Z}_{+}; \) \( G_{n}(k) \to 0 \) for \( k \in \mathbb{Z}^d, \) and \( s \lambda_{n} \Psi_{n} = O(1). \) By the LDCT, we establish

\[
\sum_{k \in \mathbb{Z}^d} \frac{G_{n}(k)}{s \lambda_{n}^{d}} |R_{0}| = o(s \lambda_{n}^{-1}); \quad E\left( \tau_{n,o,l}^{2} \right) - \tau_{n,o,l}^{2} = \Psi_{n}(1 + o(1)),
\]

representing the formulation of Theorem 4.2 in terms of \( \Psi_{n}. \) If \( V(k) \) exists for each \( k \in \mathbb{Z}^d, \) then (9.3) and (9.12) imply that we can use the LDCT again to produce

\[
\Psi_{n} = \frac{-1}{s \lambda_{n} |R_{0}|} \left( \sum_{k \in \mathbb{Z}^d} V(k) |R_{0}| \right)(1 + o(1)). \quad (9.13)
\]

The proof of Theorem 4.2 for \( \tau_{n,o,l}^{2} \) is now finished.

Consider \( \tau_{n,o,l}^{2}. \) We can repeat the same steps as above to find

\[
E\left( \tau_{n,o,l}^{2} \right) - \tau_{n,o,l}^{2} = \Psi_{n} + \sum_{k \in \mathbb{Z}^d} \frac{G_{n}(k)}{s \lambda_{n}^{d-1}} + o(s \lambda_{n}^{-1}); \quad G_{n}(k) = \frac{D_{i,n}(k) \cdot \sigma(k)}{s \lambda_{n}^{d-1}}.
\]

The same arguments for \( G_{n} \) apply to \( G_{n}^{*}, \) and (9.13) remains valid when each \( V(k) \) exists, \( k \in \mathbb{Z}^d, \) establishing Theorem 4.2 for \( \tau_{n,o,l}^{2}. \) Note as well that if \( V(k) \) exists for each \( k \in \mathbb{Z}^d, \) then Lemma 9.4 and
Lemma 4.1 also imply the second formulation of the bias in Theorem 4.2. □

Proof of Theorem 5.1: Follows from Theorems 3.1 and 4.1 and simple arguments from Calculus involving minimization of a smooth function of a real variable. □

Proof of Theorem 6.1: We develop some tools to facilitate the counting arguments required for expanding the biases of \( \tilde{\tau}_{n,ol}^2 \) and \( \tilde{\tau}_{n,sool}^2 \). We first define a count for the number of \( \mathbb{Z}^d \) lattice points lying in a “face” of a \( d \)-dimensional rectangle. For a rectangle \( R \), where \( \prod_{j=1}^{d} (c_j, \tilde{c}_j) \subseteq R \subseteq \prod_{j=1}^{d} (c_j, \tilde{c}_j) \in \mathbb{R} \), define the “border” point set: \( B(R) = \bigcup_{j=1}^{d} \{ \mathbf{s} = (s_{j_1}, \ldots, s_{j_d})' \in \mathbb{Z}^d : s_j \in \{c_j, \tilde{c}_j\} \} \). With \( k \in \mathbb{Z}^d \), it can be shown that there exists \( N_k \in \mathbb{Z}_+ \) such that: for \( n \geq N_k \),

\[
\left| B\{s \lambda_n(i + \mathbf{R}_0)\} - B\{s \lambda_n(i + \mathbf{R}_0) \cap k + s \lambda_n(i + \mathbf{R}_0)\} \right| \leq 3^{2d(d+1)} \|k\|_\infty \lambda_n^{d-2}, \quad i \in \mathbb{Z}^d. \tag{9.14}
\]

See Nordman (2002) for more details.

Fix \( k \neq 0 \in \mathbb{Z}^d \) and assume \( \min_{1 \leq j \leq d} \lambda_n \ell_j > 3 + \|k\|_\infty \). Then we write, for \( i \in \mathbb{Z}^d \), \( s_N(i) = P_{3,1,n} - P_{3,1,n} + P_{3,1,n} \), and

\[
|P_{k,n}(i)| = \left| \sum_{j=1}^{4} (P_{j-1,k,n} - P_{j,k,n}) \right|;
\]

\[
P_{3,1,n} = \prod_{j=1}^{d} \lambda_n \ell_j, \quad P_{3,1,n} = \prod_{j=1}^{d} (\lambda_n \ell_j - |\ell_j|), \quad P_{3,1,n} = B\{s \lambda_n(i + \mathbf{R}_0)\}, \quad P_{3,1,n} = B\{s \lambda_n(i + \mathbf{R}_0) \cap k + s \lambda_n(i + \mathbf{R}_0)\}.
\]

We show now that, for \( k \neq 0 \), there exists \( C > 0, N_k \in \mathbb{Z}_+ \), such that: for \( n \geq N_k \),

\[
|P_{k,n}(i)| = \left| \sum_{j=1}^{4} (P_{j-1,k,n} - P_{j,k,n}) \right| \leq C \|k\|_\infty \lambda_n^{d-2}, \quad i \in \mathbb{Z}^d. \tag{9.15}
\]

By (9.14), for large \( n \geq N_k \), we have that

\[
0 \leq \left( P_{3,1,n} - P_{3,1,n} \right) \leq \left( P_{3,1,n} - P_{3,1,n} \right) \leq C \|k\|_\infty \lambda_n^{d-2}. \]

Note that: \( \|s \lambda_n(i + \ell_j[-1/2, 1/2]) - t_j \cap \mathbb{Z} - s \lambda_n \ell_j \| \leq 3 \) for \( i \in \mathbb{Z}, j \in \{1, \ldots, d\} \). Hence,

\[
\|P_{3,1,n} - P_{3,1,n} \| \leq \sum_{A \subseteq \{1, \ldots, d\}} \|k\|_\infty \lambda_n \ell_j - \prod_{j \in A} \|s \lambda_n(i + \ell_j[-1/2, 1/2]) - t_j \cap \mathbb{Z} \| \leq C \|k\|_\infty \lambda_n^{d-2},
\]

which holds uniformly in \( i \in \mathbb{Z}^d \). With these bounds, we have (9.15).

Applying (9.15) in place of Lemma 9.4, the same proof for Theorem 4.2 establishes Theorem 6.1. □
