Abstract

In this paper we study the moment spaces corresponding to matrix measures on compact intervals and on the nonnegative line \([0, \infty)\). A representation for nonnegative definite matrix polynomials is obtained, which is used to characterize moment points by properties of generalized Hankel matrices. We also derive an explicit representation of the orthogonal polynomials with respect to a given matrix measure, which generalize the classical determinant representations of the one dimensional case. Moreover, the coefficients in the recurrence relations can be expressed explicitly in terms of the moments of the matrix measure. These results are finally used to prove a refinement of the well known Favard theorem for matrix measures, which characterizes the domain of the underlying measure of orthogonality by properties of the coefficients in the recurrence relationships.

AMS Subject Classification: 42C05  
Keywords and Phrases: Matrix measure, nonnegative definite matrix polynomials, orthogonal polynomials, canonical moments of matrix measures, Favard’s theorem

1 Introduction

Moment problems, orthogonal polynomials, continued fractions, quadrature formulas and approximation theory, etc., have been studied for a long time and have a vast literature. In recent years considerable interest has been shown in generalizing many of the results in these areas to the case of matrix polynomials and matrix measures. Among many others we refer to the early work of
Krein (1949) and to the more recent papers of Aptekarev and Nikishin (1983), Geronimo (1982), Rodman (1990), Sinap and Van Assche (1994), Duran and Van Assche (1995), Duran (1995, 1996, 1999) and Duran and Lopez-Rodriguez (1996, 1997). A \( p \times p \) matrix polynomial is a \( p \times p \) matrix with polynomial entries. It is of degree \( n \) if all the polynomials are of degree less or equal than \( n \) and is usually written in the form

\[
P(t) = \sum_{i=0}^{n} A_i t^i.
\]

where the \( A_i \) are real \( p \times p \) matrices. The matrix polynomial \( P(t) \) is called monic if the highest coefficient satisfies \( A_n = I_p \) where \( I_p \) denotes the \( p \times p \) identity matrix. A matrix measure \( \mu \) is a \( p \times p \) matrix \( \mu = \{ \mu_{ij} \} \) of finite signed measures \( \mu_{ij} \) on the Borel field of the real line \( \mathbb{R} \) or of an appropriate subset. It will be assumed here that for each Borel set \( A \) the matrix \( \mu(A) = \{ \mu_{ij}(A) \} \) is symmetric and nonnegative definite, i.e. \( \mu(A) \geq 0 \). The moments of the matrix measure \( \mu \) are given by the \( p \times p \) matrices

\[
S_k = \int t^k \, d\mu(t) \quad k = 0, 1, \ldots
\]

Only measures for which all relevant moments exist will be considered throughout this paper. The integrals will usually be over the interval \([0, 1]\) but integrals over the half line \([0, \infty)\) will also be considered in Section 5. The \((n + 1)\)th moment space is given by

\[
M_{n+1} = \{ (S_0, S_1, \ldots, S_n) \mid \mu \}
\]

where \( \mu \) ranges over the set of all matrix measures with existing moments up to the order \( n \).

The purpose of the present paper is to investigate properties of the moment space, mainly with the purpose of providing some generalizations of Favard’s Theorem in the matrix case for the nonnegative line \([0, \infty)\) and the compact interval \([0, 1]\). It is well known in the scalar case where \( p = 1 \), that if a sequence of polynomials \( \{ P_n \}_{n \geq 0} \) (where \( P_n \) is of exact degree \( n \)) is orthogonal with respect to some measure \( \mu \) on the real line, then it satisfies a three term recurrence relation of the form

\[
P_{n+1}(x) = (x - \alpha_{n+1})P_n(x) - \beta_{n+1}P_{n-1}(x) \quad n \geq 1
\]

with \( \beta_{n+1} > 0 \) [see Favard (1935)]. Conversely, if the sequence of polynomials satisfies (1.4) with \( \beta_{n+1} > 0 \) for all \( n \in \mathbb{N} \), then there exists a measure on the real line for which the polynomials are orthogonal. It is also well known that the measure \( \mu \) concentrates on the nonnegative axis \([0, \infty)\) if and only if there exists a sequence \( \{ \zeta_k \}_{k \geq 1} \) of positive numbers such that the coefficients in the recurrence relation (1.4) satisfy for all \( k \geq 1 \)

\[
\beta_{k+1} = \zeta_{2k-1}\zeta_{2k} \quad \text{and} \quad \alpha_{k+1} = \zeta_{2k} + \zeta_{2k+1}.
\]

[see e.g. Chihara (1978), p. 47]. It was further discovered by Wall (1940) that \( \mu \) is concentrated on the interval \([0, 1]\) if and only if the coefficients \( \zeta_k \) form a chain sequence; that is, they can further be decomposed as

\[
\zeta_k = q_{k-1}p_k
\]
where \( q_k = 1 - p_k \) (\( q_0 = 1 \)) and \( 0 < p_k < 1 \). The sequence of constants were called canonical moments by Skibinsky (1967, 1969, 1986) and are discussed fully in the monograph Dette and Studden (1997).

Essentially complete analogs of these results will be presented below. For the whole line (and the circle) these results are known and are discussed, for example, in Sinap and Van Assche (1996). In Section 2-4, the moments spaces \( M_{n+1} \) for measures on the interval \([0,1]\) are investigated and matrix analogs of the canonical moments are introduced. One of the main theorems in Section 2 is a representation theorem for nonnegative definite matrix polynomials, which is used to characterize the points in the moment space by properties of generalized Hankel matrices. We also present a result describing the ‘width’ of the moment space in terms of matrix valued canonical moments. In Section 3 explicit formulas for the orthogonal polynomials on the interval \([0,1]\) in the matrix case are given, which generalize the well known determinant representation for orthogonal polynomials in the case \( p = 1 \) [see e.g. Szegő (1959), p. 27]. These results are used for a discussion of the recurrence formula in more detail. Section 4 contains the generalized Favard theorem for the interval \([0,1]\). Finally, the Favard theorem for the half line, with some discussion of the corresponding moment space, is given in Section 5.

2 Moment Spaces

As indicated above, the discussion in sections 2-4 is confined to the interval \([0,1]\). The moments \( S_k \) and the moment space \( M_{n+1} \) are defined as in (1.2) and (1.3), respectively. The set \( M_{n+1} \) can be viewed as an Euclidean space of dimension \((n + 1)p(p + 1)/2\). Hyperplanes in this space may be assumed to be of the form

\[
\sum_{i=0}^{n} \text{tr}(A_i S_i) = b
\]

where \( b \in \mathbb{R} \) and the \( A_0, \ldots, A_n \) are real symmetric \( p \times p \) matrices. Consider the set

\[
C_{n+1} = \{ (aa^T, ta a^T, \ldots, t^n a a^T) \mid 0 \leq t \leq 1, \ a \in \mathbb{R}^p \}
\]

and let \( \mathcal{C}(C_{n+1}) \) denote the convex cone generated by this set. Without loss of generality we can view elements of this set as being of the form

\[
\sum_{i} \sum_{j} t_i^k d_{ij} a_{ij} a_{ij}^T
\]

where the \( d_{ij} \) are positive and \( a_{ij} \in \mathbb{R}^p \). Note that there is some redundancy here in that we could normalize the vectors \( a_{ij} \in \mathbb{R}^p \) to have length one or leave out the factors \( d_{ij} \).

**Lemma 2.1:** The set \( M_{n+1} \) defined in (1.3) is equal to the convex cone \( \mathcal{C}(C_{n+1}) \).

**Proof:** Obviously \( \mathcal{C}(C_{n+1}) \subset M_{n+1} \) and for the converse inclusion the question amounts to asking whether all the points in the moment space \( M_{n+1} \) are limits of points in the convex cone generated
above. Because the generated cone is closed, the assertion then follows. If \( \mu \) is composed of a matrix of smooth densities, say \( f \), with respect to the Lebesque measure and the integrals are viewed as Riemman integrals, then one can approximate the \( k \)th moment of \( \mu \) by

\[
(2.4) \quad \sum t_i^k f(t_i),
\]

where each \( f(t_i) \) is a nonnegative definite \( p \times p \) matrix. In this case we can write for each \( i \)

\[
(2.5) \quad f(t_i) = \sum_j d_{ij}a_{ij}a_i^T
\]

and the result follows. For the general case we use the fact that a finite number of moments of any signed measure \( \mu_{ij} \) can be approximated by one with a density of the above form.

\( \square \)

**Corollary 2.2:**

Let \( A_0, \ldots, A_n \) denote symmetric \( p \times p \) matrices, then

a) \[
\sum_{k=0}^{n} t_k A_k \geq 0 \quad \text{for all} \quad t \in [0,1] \iff \sum_{k=0}^{n} \text{tr} A_k S_k \geq 0 \quad \text{for all} \quad S = (S_0, \ldots, S_n) \in M_{n+1}.
\]

b) Every point \( S = (S_0, \ldots, S_n) \) in the moment space \( M_{n+1} \) has a finite representation of the form

\[
S_k = \sum_{i=1}^{q} d_i a_i a_i^T t_i^k \quad k = 0, \ldots, n
\]

where the number of terms in these representations is bounded by

\[
q \leq (n + 1) \frac{p(p+1)}{2}.
\]

c) Every point in the interior of the moment space \( M_{n+1} \) has a representation of the above form using any specific pair \( (t, a) \in [0,1] \times \mathbb{R}^p \).

**Proof:** The proof for part a) follows by noting that

\[
\sum_{k=0}^{n} t_k A_k \geq 0 \quad \text{for all} \quad t \in [0,1] \iff \sum_{k=0}^{n} t_k^k A_k a \geq 0 \quad \text{for all} \quad a \in \mathbb{R}^p \text{ and } t \in [0,1]
\]

\[
\iff \sum_{k=0}^{n} \text{tr}(A_k t_k a a^T) \geq 0 \quad \text{for all} \quad a \in \mathbb{R}^p \text{ and } t \in [0,1]
\]

\[
\iff \sum_{k=0}^{n} \text{tr}(A_k S_k) \geq 0 \quad \text{for all} \quad (S_0, \ldots, S_n) \in M_{n+1}.
\]
where \( trB \) denotes the trace of the matrix \( B \) and the last equivalence follows from Lemma 2.1. Part b) follows from the Caratheodory theorem [see e.g. Rockafellar (1970)].

For part c) we take the line joining the point corresponding to \((t, a)\) and the interior point and extend it past the interior point to the boundary. Therefore we are able to write the interior point as a bona fide convex combination of the point corresponding to \((t, a)\) and some other point. 

\[ \square \]

**Lemma 2.3:** Let \( S = (S_0, \ldots, S_n) \in M_{n+1} \), then

a) \( S \in M_{n+1} \) if and only if

\[
\sum_{k=0}^{n} t^k A_k \geq 0 \quad \text{for all } t \in [0, 1] \implies \sum_{k=0}^{n} tr S_k A_k \geq 0
\]

b) \( S \in Int(M_{n+1}) \) if and only if

\[
P(t) = \sum_{k=0}^{n} t^k A_k \geq 0 \quad \text{for all } t \in [0, 1] \quad \text{and} \quad P(t) \text{ is not the zero matrix for all } t \in [0, 1] \implies \sum_{k=0}^{n} tr S_k A_k > 0
\]

**Proof:** For part a) the necessity follows directly from Corollary 2.2. We now show sufficiency proving that \( S^o \not\in M_{n+1} \) implies the converse of (2.6). To this end assume that \( S^o = (S_0^o, \ldots, S_n^o) \) is not in the moment space \( M_{n+1} \). By Corollary 2.2 there exists matrices \( A_0, \ldots, A_n \) (symmetric) with

\[
\sum_{k=0}^{n} tr A_k S_k^o < 0
\]

and

\[
\sum_{k=0}^{n} tr A_k S_k \geq 0 \quad \text{for all } S = (S_0, \ldots, S_n) \in M_{n+1}.
\]

These latter inequalities include

\[
\sum_{k=0}^{n} tr A_k t^k a a^T \geq 0 \quad \forall \quad a \in \mathbb{R}^p, t \in [0, 1].
\]

Thus we have

\[
\sum_{k=0}^{n} t^k A_k \geq 0 \quad \forall \quad t \in [0, 1] \quad \text{but} \quad \sum_{k=0}^{n} tr A_k S_k^o < 0
\]

or (2.6) is not true.

To prove part b) we first suppose that \( S = (S_0, \ldots, S_n) \) is in the interior of moment space \( M_{n+1} \) and \( P(t) \) is not identically zero for all \( t \). Then for some \( t \), there is a vector \( a \in \mathbb{R}^p \) such that \( a^T P(t)a \) is positive. We now take the representation of \( S \) from part c) of Corollary 2.2 which involves \( t \) and \( a \) to show that \( \sum_{k=0}^{n} tr S_k A_k > 0 \). For the converse we suppose that \( S \) is not in the interior of \( M_{n+1} \). In this case there exists a nontrivial polynomial \( P(t) = \sum_{k=0}^{n} t^k A_k \geq 0 \) such that \( \sum_{k=0}^{n} tr A_k S_k \leq 0 \). 

\[ \square \]
Remark 2.4: When normalizing the coefficients in the representations it seems like a good choice is to take the points \( S = (S_0, \ldots, S_n) \in M_{n+1} \) satisfying \( trS_0 = 1 \). Thus we let \( C_n^0 \) denote the subset of \( C_{n+1} \) defined in (2.2) where \( a^T a = 1 \) and \( M_n^0 \) be the subset of \( M_{n+1} \) where \( trS_0 = 1 \). It is fairly easy to show that \( M_n^0 \) is the convex hull of \( C_n^0 \). To do this we note that the convex hull of \( C_n^0 \) is contained in \( M_n^0 \). Further, if one is using pairs \((d_i, a_i)\) in the representation \( (2.3) \) we can get the same point by replacing \( d_i \) by \( ||a_i||_2^2 d_i \) and \( a_i \) by \( a_i/||a_i||_2 \) where \( ||\cdot||_2 \) is the euclidean norm of \( a_i \in \mathbb{R}^p \).

Karlin-Studden (1966) discuss taking sections of the moment cones which are the intersection of the cone with some affine space to produce normalizations. These are generated by positive polynomials. The usual normalization in the scalar case takes the polynomial \( P(t) = 1 \) to give \( \lambda_0 = 1 \) or the measures with norm one. If we take the matrix polynomial \( P(t) = I \) we get the above normalization where \( trS_0 = 1 \).

The next theorem gives a representation for nonnegative definite \( p \times p \) matrix polynomials

\[
P_n(t) = \sum_{k=0}^{n} t^k A_k \geq 0
\]

on the interval \([0, 1]\).

**Theorem 2.5:** Assume that the matrix polynomial \( P_n(t) \) is nonnegative definite for all \( t \) in the interval \([0, 1]\).

If \( n = 2m \), then there exist matrix polynomials \( B_n(t) = \sum_{i=0}^{m} B_i t^i \), \( C_{m-1}(t) = \sum_{i=0}^{m-1} C_i t^i \) such that

\[
P_{2m}(t) = B_m(t)B_m(t)^T + t(1-t)C_{m-1}(t)C_{m-1}(t)^T
\]

\[
= \sum_{k=1}^{p} \left[ \sum_{i=0}^{m} b_{ik} t^i \left( \sum_{i=0}^{m} b_{ik} t^i \right)^T + t(1-t) \left( \sum_{i=0}^{m-1} c_{ik} t^i \right) \left( \sum_{i=0}^{m-1} c_{ik} t^i \right)^T \right].
\]

If \( n = 2m + 1 \), then there exist matrix polynomials \( B_m(t) = \sum_{i=0}^{m} B_i t^i \), \( C_m(t) = \sum_{i=0}^{m} C_i t^i \) such that

\[
P_{2m+1}(t) = tB_m(t)B_m(t)^T + (1-t)C_m(t)C_m(t)^T
\]

\[
= \sum_{k=1}^{p} \left[ t \left( \sum_{i=0}^{m} b_{ik} t^i \right) \left( \sum_{i=0}^{m} b_{ik} t^i \right)^T + (1-t) \left( \sum_{i=0}^{m} c_{ik} t^i \right) \left( \sum_{i=0}^{m} c_{ik} t^i \right)^T \right].
\]

Here \((b_{i1}, \ldots, b_{ip}) = B_i \) and \((c_{i1}, \ldots, c_{ip}) = C_i \) denote the columns of the coefficients \( B_i \) and \( C_i \) in the matrix polynomials \( B_m(t) \), \( C_{m-1}(t) \) and \( C_m(t) \), respectively.

**Proof:** The proof follows from the corresponding results for trigonometric polynomials given by Malyshev (1982) [see also Rosenblatt (1956)]. This results states that if the matrix trigonometric
polynomial satisfies

\begin{equation}
A(\varphi) = \sum_{k=-N}^{N} A_k e^{ik\varphi} > 0
\end{equation}

for all \( \varphi \in \mathbb{R} \), where \( A_0, \ldots, A_N \) are complex \( p \times p \) matrices satisfying \( A_k = A_k^* \) \( (k = 0, \ldots, N) \), then there exists a unique matrix polynomial \( \sum_{k=0}^{N} D_k e^{ik\varphi} \) with \( D_0 = D_0^* > 0 \) and \( \det \sum_{k=0}^{N} D_k \lambda^k \neq 0 \) for all \( |\lambda| \leq 1 \) such that the polynomial \( A \) can be represented as

\begin{equation}
A(\varphi) = D(\varphi)D(\varphi)^*.
\end{equation}

Moreover, if \( A(\varphi) \) is semidefinite the representation (2.9) also exists, but the polynomial \( D \) is not necessarily unique. The proof given by Malyshev (1982) can be easily extended to show that if \( A_0, \ldots, A_N \) are real symmetric matrices and \( A_{-k} = A_k \) \( (k = 1, \ldots, N) \), then a representation of the form (2.9) also exists, where the coefficients of the matrix polynomial \( D \) are real matrices.

With this result in hand the proof of Theorem 2.5 follows by similar arguments as given in Szegö (1959), Theorem 1.21.1 or in Dette and Studden (1997), Remark 9.2.9. To be precise let \( P(t) \) denote a nonnegative definite matrix polynomial of degree \( 2m \) on the interval \([-1, 1]\) and put \( t = \cos \varphi \). Because \( P(\cos \varphi) \) is a cosine polynomial of degree \( 2m \) it follows that it has a representation of the form

\begin{equation}
P(\cos \varphi) = \sum_{k=-2m}^{2m} A_k e^{ik\varphi} \geq 0,
\end{equation}

where the coefficients satisfy \( A_{-k} = A_k \). Consequently, the generalization of Malyshev’s result yields

\begin{equation}
P(\cos \varphi) = D(\varphi)D(\varphi)^* = \left(D(\varphi)e^{-im\varphi}\right)\left(D(\varphi)e^{-im\varphi}\right)^*
\end{equation}

for a real matrix polynomial \( D(t) = \sum_{k=0}^{2m} D_k t^k \) of degree \( 2m \). Now

\begin{equation}
D(\varphi)e^{-im\varphi} = \sum_{k=0}^{2m} D_k e^{i(k-m)\varphi} = B_m(\cos \varphi) + i \sin \varphi C_{m-1}(\cos \varphi),
\end{equation}

where \( B_m \) and \( C_{m-1} \) are real matrix polynomials of degree \( m \) and \( m-1 \), respectively. This gives for the polynomial in (2.10)

\begin{equation}
P(\cos \varphi) = B_m(\cos \varphi)B_m^T(\cos \varphi) + (\sin \varphi)^2 C_{m-1}(\cos \varphi)C_{m-1}^T(\cos \varphi)
\end{equation}

\begin{equation*}
+ i \sin \varphi \left\{ C_{m-1}(\cos \varphi)B_m^T(\cos \varphi) - B_m(\cos \varphi)C_{m-1}^T(\cos \varphi) \right\}
\end{equation*}

\begin{equation}
= B_m(\cos \varphi)B_m^T(\cos \varphi) + (\sin \varphi)^2 C_{m-1}(\cos \varphi)C_{m-1}^T(\cos \varphi),
\end{equation}

where the last equality follows from the fact that the left hand side of the above equation is a real matrix polynomial in \( \cos \varphi \). This proves the assertion of Theorem 2.5 in the case \( n = 2m \) for the interval \([-1, 1]\). The transformation to the interval \([0, 1]\) is obvious and the remaining case \( n = 2m + 1 \) follows by similar arguments. \( \square \)
Theorem 2.5 together with Lemma 2.3 now gives us necessary and sufficient conditions for the point \( S = (S_0, \ldots, S_n) \) to belong to the moment space \( M_{n+1} \) or to its interior. To this end we define the "Hankel" matrices

\[
H_{2m} = \begin{pmatrix}
S_0 & \cdots & S_m \\
\vdots & \ddots & \vdots \\
S_m & \cdots & S_{2m}
\end{pmatrix},
\quad \overline{H}_{2m} = \begin{pmatrix}
S_1 - S_2 & \cdots & S_m - S_{m+1} \\
\vdots & \ddots & \vdots \\
S_m - S_{m+1} & \cdots & S_{2m-1} - S_{2m}
\end{pmatrix}
\]

and

\[
H_{2m+1} = \begin{pmatrix}
S_1 & \cdots & S_{m+1} \\
\vdots & \ddots & \vdots \\
S_{m+1} & \cdots & S_{2m+1}
\end{pmatrix},
\quad \overline{H}_{2m+1} = \begin{pmatrix}
S_0 - S_1 & \cdots & S_m - S_{m+1} \\
\vdots & \ddots & \vdots \\
S_m - S_{m+1} & \cdots & S_{2m-1} - S_{2m+1}
\end{pmatrix}
\]

and obtain the following characterization.

**Theorem 2.6:**

a) The point \( (S_0, \ldots, S_n) \) is in the moment space \( M_{n+1} \) if and only if the matrices \( H_n \) and \( \overline{H}_n \) are nonnegative definite.

b) The point \( S = (S_0, \ldots, S_n) \) is in the interior of the moment space \( M_{n+1} \) if and only if the matrices \( H_n \) and \( \overline{H}_n \) are positive definite.

The nonnegativity of the matrices \( H_n \) and \( \overline{H}_n \) impose limits on the moments \( S_k \) as is the one dimensional case. To be precise let

\[
h_{2m}^{T} = (S_{m+1}, \ldots, S_{2m})
\]

\[
h_{2m-1}^{T} = (S_{m}, \ldots, S_{2m-1})
\]

\[
\overline{h}_{2m}^{T} = (S_{m} - S_{m+1}, \ldots, S_{2m-1} - S_{2m})
\]

\[
\overline{h}_{2m-1}^{T} = (S_{m} - S_{m+1}, \ldots, S_{2m-2} - S_{2m-1})
\]

and define \( S_{1}^{-} = 0 \) and

\[
S_{n+1}^{-} = h_n^{T} \overline{H}_{n-1}^{-1} h_n, \quad n \geq 1,
\]

and \( S_{1}^{+} = S_{0}, \ S_{2}^{+} = S_{1} \) and

\[
S_{n+1}^{+} = S_{n} - \overline{h}_n^{T} \overline{H}_{n-1}^{-1} \overline{h}_n, \quad n \geq 2,
\]

whenever the inverses of the Hankel matrices exist. It is to be noted and stressed that \( S_{n}^{-} \) and \( S_{n}^{+} \) depend on \( (S_0, S_1, \ldots, S_{n-1}) \) although this is not mentioned explicitly. It follows from Theorem 2.6 and a straightforward calculation with partitioned matrices that \( (S_0, \ldots, S_{n-1}) \) is in the interior of the moment space \( M_n \) if and only if \( S_{n}^{-} < S_{n}^{+} \) (note that a matrix is positive definite if and only if its main subblock and the corresponding Schur complement are positive definite). Moreover, for \( (S_0, \ldots, S_n) \in M_{n+1} \) we have

\[
S_{n}^{-} \leq S_{n} \leq S_{n}^{+}.
\]
If \((S_0, S_1, \ldots, S_{n-1})\) is in the interior of the moment space \(M_n\), then we define the \(k\)th matrix canonical moment as the matrix

\[
P_k = D_k^{-1}(S_k - S_k^-), \quad 1 \leq k \leq n,
\]

where

\[
D_k = S_k^+ - S_k^-.
\]

These quantities are the analog of the classical canonical moments \(p_n\) in the scalar case [see Skibinsky (1967, 1969, 1986) or Dette and Studen (1997)]. We will also make use of the quantities

\[
Q_k = I - P_k = D_k^{-1}(S_k^+ - S_k) , \quad 1 \leq k \leq n.
\]

The canonical moments of lower order can easily be calculated. From \(S_1^+ = S_0\), \(S_1^- = 0\) we have \(D_1 = S_0\) and \(P_1 = S_0^{-1}S_1\). Similarly, the definitions (2.13) and (2.14) imply

\[
S_2^+ = S_1^+ = S_1
\]

\[
S_2^- = S_1S_0^{-1}S_1
\]

which gives

\[
D_2 = S_1(I_p - S_0^{-1}S_1) = S_1(I_p - P_1) = S_1Q_1
\]

and

\[
P_2 = (I_p - S_0^{-1}S_1)^{-1}S_1^{-1}(S_2 - S_1S_0^{-1}S_1).
\]

One of our main theorems in this section is the following result, which represents the width \(D_{n+1}\) of the moment space \(M_{n+1}\) in terms of the matrix canonical moments \(P_k\) and \(Q_k\).

**Theorem 2.7:** If the point \((S_0, \ldots, S_n)\) is in the interior of the moment space \(M_{n+1}\), then

\[
D_{n+1} = S_0P_1Q_1P_2Q_2\cdots P_nQ_n
\]

and

\[
P_kQ_k = Q_kP_k, \quad \text{for} \quad k = 1, \ldots, n.
\]

**Proof.** The proof will follow if we can show the representations

\[
S_{n+1}^+ - S_{n+1}^- = (S_n^+ - S_n)(S_{n+1}^+ - S_{n+1}^-)^{-1}(S_n^+ - S_n^-)(S_{n-1} - S_{n-1}^-)^{-1}(S_n - S_n^-)
\]

or equivalently

\[
S_{n+1}^+ - S_{n+1}^- = (S_n^+ - S_n)[(S_{n+1}^+ - S_{n+1}^-)^{-1} + (S_{n-1} - S_{n-1}^-)^{-1}](S_n - S_n^-).
\]

Assuming that (2.20) is true we can obtain the assertion of Theorem 2.7 by a simple induction argument. Note that \(D_1 = S_1^+ - S_1^- = S_0\) and using \(P_1 = S_0^{-1}S_1\) we find that \(P_1Q_1 = Q_1P_1\) and

\[
D_2 = S_2^+ - S_2^- = S_1 - S_1S_0^{-1}S_1 = S_0P_1Q_1 = S_0Q_1P_1.
\]
Proceeding by induction we can then show that
\[
D_{n+1} = D_n Q_n (D_{n-1} Q_{n-1})^{-1} D_{n-1} (D_{n-1} P_{n-1})^{-1} D_n P_n
\]
\[
= D_n Q_n Q_{n-1}^{-1} P_{n-1}^{-1} D_{n-1} D_n P_n
\]
\[
= D_n Q_n P_n
\]
where the first equality follows from (2.20), (2.16), (2.18) and the last is a consequence of the induction hypothesis. Noting that all the terms in (2.13) - (2.17) are symmetric, it also follows that
\[
D_{n+1} = (S_n - S_n^-) (S_{n-1} - S_{n-1}^-)^{-1} (S_{n-1}^+ - S_{n-1}^-) (S_n^+ - S_n^-)
\]
\[
= D_n P_n (D_{n-1} P_{n-1})^{-1} D_{n-1} (D_{n-1} Q_{n-1})^{-1} D_n Q_n
\]
\[
= D_n P_n Q_n
\]
in which case \( P_n Q_n = Q_n P_n \).

Proof of the identities (2.20) and (2.21): From the definition (2.13) and (2.14) we have
\[
(2.22) \quad S_{n+1}^+ - S_{n+1}^- = S_n - \bar{h}_n^T \bar{H}_{n-1}^{-1} \bar{h}_n - \bar{h}_n^T \bar{H}_{n-1}^{-1} \bar{h}_n
\]
To show (2.21) we want to factor a term \( S_n - S_n^- \) from the right and a term \( S_n^+ - S_n \) from the left
and leave the appropriate thing in the middle to give the identity (2.21). This will follow, with some further explanation, from the following two interesting results. To be precise let \( \bar{h}_n(-) \) and \( \bar{r}_n(-) \) be the value of \( \bar{h}_n \) and \( \bar{r}_n \), respectively, where the last moment matrix \( S_n \) is changed to \( S_n^- \).
Similary, \( \bar{h}_n(+) \) and \( \bar{r}_n(+) \) are obtained from \( \bar{h}_n \) and \( \bar{r}_n \), replacing the last moment matrix \( S_n \) by \( S_n^+ \), respectively and we define \( \bar{g}_n \) and \( \bar{q}_n \) in the same manner as \( \bar{h}_n \) and \( \bar{r}_n \) where all matrices \( S_k \) are replaced by arbitrary elements \( G_k \in \mathbb{R}^{p \times p} \). We will show below that the identities
\[
(2.23) \quad S_n^- - \bar{h}_n^T \bar{H}_{n-1}^{-1} \bar{h}_n(-) - \bar{r}_n^T \bar{H}_{n-1}^{-1} \bar{r}_n(-) = 0
\]
and
\[
(2.24) \quad G_n - \bar{h}_n^T (+) \bar{H}_{n-1}^{-1} \bar{g}_n - \bar{r}_n^T (+) \bar{H}_{n-1}^{-1} \bar{q}_n = 0
\]
hold for all \( \bar{g}_n \) and \( \bar{q}_n \). Note carefully in the last equation that the leading matrix \( G_n \) of equation (2.24) is the same \( G_n \) in the last coordinate of \( \bar{g}_n \) and \( \bar{q}_n \).

Once we have established the validity of (2.23) and (2.24) we start with the expression for \( S_{n+1}^+ - S_{n+1}^- \) in (2.22) and rewrite \( S_n = S_n - S_n^- + S_n^- \) for the first matrix \( S_n \) in (2.22) and on the right side of the two quadratic forms. Using the identity (2.23) we can factor the matrix \( S_n - S_n^- \) from the right side and the result is
\[
(2.25) \quad S_{n+1}^+ - S_{n+1}^- = \left[ I_p - \bar{h}_n^T \bar{H}_{n-1}^{-1} (0, \ldots, 0, -I_p)^T - \bar{r}_n^T \bar{H}_{n-1}^{-1} (0, \ldots, 0, I_p)^T \right] (S_n - S_n^-)
\]
This resulting expression can be further simplified rewriting \( S_n = S_n^+ + S_n^\perp \) on the left side of what remains of the two quadratic forms. Using (2.24) (applied by setting on the right side of the quadratic forms \( G_n = I_p \) and the other \( G_k \) values equal to zero in \( g_n \) and \( q_n \)) and the definition (2.13) and (2.14) everything cancels and we are left with (2.21).

**Proof of the identities (2.23) and (2.24):** To see the proof of (2.23) and (2.24) we consider only the case where \( n = 2m \), the odd case being similar. For \( n = 2m \) we have to show that

\[
(2.26) \quad R_m = S_{2m}^- - \left( \begin{array}{c}
S_m \\
\vdots \\
S_{2m-1} \\
S_{2m}
\end{array} \right) \left( \begin{array}{ccccc}
S_0 - S_1 & \cdots & S_{m-1} - S_m \\
\vdots & & \vdots & & \vdots \\
S_{m-1} - S_m & \cdots & S_{2m-2} - S_{2m-1}
\end{array} \right)^{-1} \left( \begin{array}{c}
S_m \\
\vdots \\
S_{2m-1} \\
S_{2m}
\end{array} \right)
\]

which is equivalent to (2.23) by the definition (2.11) and (2.12). To this end we write the column vectors on the right side of the two quadratic forms in the above expression in a convenient form. From the definition of the matrix \( S_{2m}^- \) in (2.13) we obtain the representation

\[
\left( \begin{array}{c}
S_m \\
\vdots \\
S_{2m-1} \\
S_{2m}
\end{array} \right) = \left( \begin{array}{ccccc}
S_0 & \cdots & S_{m-1} \\
\vdots & & \vdots & & \vdots \\
S_{m-1} & \cdots & S_{2m-2}
\end{array} \right)^{-1} \left( \begin{array}{c}
S_m \\
\vdots \\
S_{2m-1} \\
S_{2m}
\end{array} \right).
\]

Taking differences and omitting the first component it follows that

\[
(2.27) \quad \left( \begin{array}{c}
S_m - S_{m+1} \\
\vdots \\
S_{2m-1} - S_{2m}
\end{array} \right) = \left( \begin{array}{ccccc}
S_0 - S_1 & \cdots & S_{m-1} - S_m \\
\vdots & & \vdots & & \vdots \\
S_{m-1} - S_m & \cdots & S_{2m-2} - S_{2m-1}
\end{array} \right)^{-1} \left( \begin{array}{c}
S_m \\
\vdots \\
S_{2m-1} \\
S_{2m}
\end{array} \right)
\]

and

\[
(2.28) \quad \left( \begin{array}{c}
S_{m+1} \\
\vdots \\
S_{2m-1} \\
S_{2m}
\end{array} \right) = \left( \begin{array}{ccccc}
S_1 & \cdots & S_m \\
\vdots & & \vdots & & \vdots \\
S_{m-1} & \cdots & S_{2m-2}
\end{array} \right)^{-1} \left( \begin{array}{c}
S_m \\
\vdots \\
S_{2m-1} \\
S_{2m}
\end{array} \right).
\]

Substituting (2.27) and (2.28) into (2.26) we find that (2.26) becomes

\[
R_m = S_{2m}^- - \left( \begin{array}{c}
S_m - S_{m+1} \\
\vdots \\
S_{2m-1} - S_{2m}
\end{array} \right) \left( \begin{array}{ccccc}
S_0 & \cdots & S_{m-1} \\
\vdots & & \vdots & & \vdots \\
S_{m-1} & \cdots & S_{2m-2}
\end{array} \right)^{-1} \left( \begin{array}{c}
S_m \\
\vdots \\
S_{2m-1} \\
S_{2m}
\end{array} \right)
\]

11
Now separate the vector on the left in the first quadratic form. One part will cancel with the second quadratic form and the rest will be zero from the definition of $S_{2m}^+$, which proves the identity (2.26).

To verify the equation (2.24) the argument is essentially the same but slightly more complicated. We need to verify that

$$
\tilde{R}_m = G_{2m} - \begin{pmatrix} S_m - S_{m+1} \\ \vdots \\ S_{2m-1} - S_{2m}^+ \end{pmatrix}^T \begin{pmatrix} S_0 - S_1 & \cdots & S_{m-1} - S_m \\ \vdots & \vdots & \vdots \\ S_{m-1} - S_m & \cdots & S_{2m-2} - S_{2m-1} \end{pmatrix}^{-1} \begin{pmatrix} G_m - G_{m+1} \\ \vdots \\ G_{2m-1} - G_{2m} \end{pmatrix}
$$

$$
- \begin{pmatrix} S_{m+1} \\ \vdots \\ S_{2m}^+ \end{pmatrix}^T \begin{pmatrix} S_1 & \cdots & S_m \\ \vdots & \vdots & \vdots \\ S_{m-1} & \cdots & S_{2m-1} \end{pmatrix}^{-1} \begin{pmatrix} G_{m+1} \\ \vdots \\ G_{2m} \end{pmatrix} = 0
$$

holds for all matrices $G_m, \ldots, G_{2m}$. From the definition of the matrix $S_{2m}^+$ in (2.14) we get

$$
\begin{pmatrix} S_m - S_{m+1} \\ \vdots \\ S_{2m-1} - S_{2m}^+ \end{pmatrix}^T = \begin{pmatrix} S_m - S_{m+1} \\ \vdots \\ S_{2m-2} - S_{2m-1} \end{pmatrix}^T \begin{pmatrix} S_1 - S_2 & \cdots & S_{m-1} - S_m \\ \vdots & \vdots & \vdots \\ S_{m-1} - S_m & \cdots & S_{2m-3} - S_{2m-2} \end{pmatrix}^{-1} \times

\begin{pmatrix} S_1 - S_2 & \cdots & S_{m-1} - S_m & S_m - S_{m+1} \\ \vdots & \vdots & \vdots & \vdots \\ S_{m-1} - S_m & \cdots & S_{2m-3} - S_{2m-2} & S_{2m-2} - S_{2m-1} \end{pmatrix}
$$

which can be rewritten as

$$
\begin{pmatrix} S_{m+1} \\ \vdots \\ S_{2m}^+ \end{pmatrix}^T = \begin{pmatrix} S_m \\ \vdots \\ S_{2m-2} - S_{2m-1} \end{pmatrix}^T \begin{pmatrix} S_1 - S_2 & \cdots & S_{m-1} - S_m \\ \vdots & \vdots & \vdots \\ S_{m-1} - S_m & \cdots & S_{2m-3} - S_{2m-2} \end{pmatrix}^{-1} \times

D(m-1,m)
$$

where

$$
D(m-1,m) = \begin{pmatrix} I_p & -I_p & 0 & 0 & \cdots \\ 0 & I_p & -I_p & 0 & \cdots \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & 0 & 0 & I_p & -I_p \end{pmatrix}
$$

12
is a block differencing matrix of size \((m - 1)p^2 \times mp^2\). Substituting (2.30) and (2.31) into (2.29) yields

\[
\hat{R}_m = G_{2m} - \begin{pmatrix}
S_m - S_{m+1} \\
\vdots \\
S_{2m-2} - S_{2m-1}
\end{pmatrix}^T \begin{pmatrix}
S_1 - S_2 & \cdots & S_{m-1} - S_m \\
\vdots & & \vdots \\
S_{m-1} - S_m & \cdots & S_{2m-3} - S_{2m-2}
\end{pmatrix}^{-1}
\times \begin{pmatrix}
0 & I_p & 0 & \cdots \\
0 & 0 & I_p & \\
\vdots & & & \\
0 & 0 & 0 & I_p
\end{pmatrix}
\begin{pmatrix}
G_m - G_{m+1} \\
\vdots \\
G_{2m-1} - G_{2m}
\end{pmatrix}
\]

(2.32)

\[
\begin{pmatrix}
S_m \\
\vdots \\
S_{2m-1}
\end{pmatrix}^T \begin{pmatrix}
S_1 & \cdots & S_m \\
\vdots & & \vdots \\
S_m & \cdots & S_{2m-1}
\end{pmatrix}^{-1} \begin{pmatrix}
G_{m+1} \\
\vdots \\
G_{2m}
\end{pmatrix}
\]

\[
+ \begin{pmatrix}
S_m - S_{m+1} \\
\vdots \\
S_{2m-2} - S_{2m-1}
\end{pmatrix}^T \begin{pmatrix}
S_1 - S_2 & \cdots & S_{m-1} - S_m \\
\vdots & & \vdots \\
S_{m-1} - S_m & \cdots & S_{2m-3} - S_{2m-2}
\end{pmatrix}^{-1} \begin{pmatrix}
G_{m+1} - G_{m+2} \\
\vdots \\
G_{2m-1} - G_{2m}
\end{pmatrix}
\]

This is zero since the first and second terms cancel with the third and fourth, respectively. This proves the identity (2.24) and completes the proof of the theorem.

\[\square\]

For later use we note that Theorem 2.7 implies, using an induction argument, that the following important result holds.

**Theorem 2.8:** If for some \(n \geq 1\), the point \((S_0, S_1, \cdots, S_n)\) is in the interior of the moment space \(M_{n+1}\) then \((S_0^- = 0, Q_0 = I_p)\)

\[
(S_n^- - S_{n-1}^-)(S_n - S_n^-) = Q_{n-1}P_n =: \zeta_n
\]

\[
(S_n^+ - S_{n-1}^-)^{-1}(S_n^+ - S_n) = P_{n-1}Q_n =: \gamma_n
\]

**Proof.** The result follows since from Theorem 2.7 and (2.16) we have

\[
S_n - S_n^- = D_nP_n = S_0P_1Q_1 \cdots P_{n-1}Q_{n-1}P_n > 0
\]

and

\[
S_n^+ - S_n = D_nQ_n = S_0P_1Q_1 \cdots Q_{n-1}P_{n-1}Q_n > 0
\]

\[\square\]

13
Example 2.9: Consider the matrix measure

\[
\mu = \begin{pmatrix} \mu_{11} & \mu_{12} \\ \mu_{12} & \mu_{22} \end{pmatrix}
\]

where

\[
\frac{d\mu_{11}}{dt} = \frac{d\mu_{22}}{dt} = \frac{1}{\pi} \frac{1}{\sqrt{t(1-t)}}
\]

\[
\frac{d\mu_{12}}{dt} = \frac{1}{\pi} \frac{2t-1}{\sqrt{t(1-t)}}
\]

[see also Van Assche (1993), who considered this example on the interval \([-1, 1]\). A straightforward calculation shows]

\[
S_k = \binom{2k}{k} \frac{1}{2^{2k}(k+1)} \begin{pmatrix} k+1 & k \\ k & k+1 \end{pmatrix}, \quad k \geq 0,
\]

which gives for the first canonical moments

\[
P_1 = S_0^{-1} S_1 = \begin{pmatrix} \frac{1}{2} & \frac{1}{2} \\ \frac{1}{2} & \frac{1}{2} \end{pmatrix}, \quad P_2 = \begin{pmatrix} \frac{1}{3} & 0 \\ 0 & \frac{1}{3} \end{pmatrix}.
\]

It can be shown by tedious computations that the canonical moments of the matrix measure \(\mu\) are given by

\[
P_{2k} = \frac{k}{2k+1} \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \quad P_{2k-1} = \frac{1}{2} \begin{pmatrix} 1 & \frac{1}{2k} \\ \frac{1}{2k} & 1 \end{pmatrix},
\]

for \(k \in \mathbb{N}\).

3 Orthogonal Polynomials

The inner product of two matrix polynomials is defined by

\[
< P, Q > = \int P^T(t)\mu(dt)Q(t).
\]

Sinap and Van Assche (1996) call this the 'right' inner product. The left inner product would put the transpose of the Q polynomial. The orthogonal polynomials are defined by orthogonalizing the sequence \(I_p, tI_p, t^2I_p, \cdots\) with respect to the above inner product. As the main result of this section we will write down explicitly the orthogonal polynomials somewhat in the fashion of the one-dimensional case. In the case \(p = 1\) the last row of the determinant

\[
D_{2m} = \begin{vmatrix} S_0 & \cdots & S_m \\ \vdots & \vdots \\ S_m & \cdots & S_{2m} \end{vmatrix}
\]

14
is changed by replacing it by \((1, t, \cdots, t^m)\) [see e.g. Szegö (1959)]. The general case \(p \geq 2\) is substantially more complicated, because \(P_m(t)\) is a matrix of polynomials each of degree \(m\). To get the element in the position \((i, j)\) of the matrix of \(P_m(t)\) we write each of these by again modifying the above determinant by changing the last set of blocks \((S_m, \cdots, S_{2m})\).

To be precise define a matrix polynomial by

\[
P_m(t) = \mathcal{H}_{2m-1}(t) = (H_{ij}(t))_{i,j=1}^{p}
\]

where the elements \(H_{ij}(t)\) are determinants given by

\[
H_{ij}(t) = \begin{vmatrix}
S_0 & S_1 & \cdots & S_m \\
S_{m-1} & S_m & \cdots & S_{2m-1} \\
S_{m} & S_{m+1} & \cdots & S_{2m}
\end{vmatrix}
\]

and the matrix \(S_{m+k}^{ij}\) is obtained from \(S_{m+k}\) replacing the \(j\)th row by \(e_i^T e_k\). Here \(e_i \in \mathbb{R}^p\) denotes the vector with a one in the \(i\)th component and zero elsewhere.

As a simple example consider the case \(m = 1\) and \(p = 2\) and let \(S_k = (s_{k,ij})_{i,j=1}^{p}\) denote the elements of the \(k\)th moment matrix. In this case the linear polynomial is given by the \(2 \times 2\) matrix of determinants

\[
P_1(t) = \mathcal{H}_1(t) = \begin{vmatrix}
(s_{0,11} & s_{0,12} & s_{0,11} & s_{0,12}) \\
(s_{0,21} & s_{0,22}) & (s_{1,11} & s_{1,12}) & (s_{0,21} & s_{0,22}) & (s_{1,11} & s_{1,12}) \\
1 & 0 & t & 0 & 1 & 0 & t & 0 \\
(s_{1,21} & s_{1,22}) & (s_{2,11} & s_{2,12}) & (s_{2,21} & s_{2,22}) & (s_{2,11} & s_{2,12}) & (s_{2,21} & s_{2,22}) & (s_{2,11} & s_{2,12}) & (s_{2,21} & s_{2,22}) & (s_{2,11} & s_{2,12})
\end{vmatrix}
\]

The following result shows that the polynomials \(P_j(t)\) are the right orthogonal matrix polynomials with respect to the inner product defined by (3.1) and identifies the leading coefficient of \(P_m(t)\), i.e. the matrix of the term \(t^m\).

**Theorem 3.1:** The polynomial \(P_m(t) = \mathcal{H}_{2m-1}(t)\) is the \(m\)th matrix orthogonal polynomial with respect to the inner product (3.1) and has leading coefficient

\[
L_m = \mathcal{D}_{2m}(S_{2m} - S_{2m}^{-1}),
\]

where the determinant \(\mathcal{D}_{2m}\) is defined in (3.2).
Proof: It is required to show that
\[ B = \int_0^1 t^k d\mu(t) H_{2m-1}(t) = 0 \in \mathbb{R}^{p \times p}, \quad \text{for all } k = 0, 1, \ldots, m - 1. \]

For the element in the position \((i, j)\) of this matrix we obtain
\[ B_{ij} = \sum_{l=1}^p \int_0^1 H_{ij}(t) t^k d\mu(t) \]
and a straightforward calculation shows that this is equal to the determinant \(D_{2m}\) with the \(j\)th row replaced by
\[ \int_0^1 t^k (d\mu_{i1}, \ldots, d\mu_{ip}), \ldots, \int_0^1 t^{k+m}(d\mu_{i1}, \ldots, d\mu_{ip}). \]

For this reason \(B_{ij}\) is zero because this is the \(i\)th row of \((S_k, \ldots, S_{k+m})\), provided \(k < m\). If \(k = m\), we have by the same argument that if \(i \neq j\), \(B_{ij} = 0\) (because here the block corresponding to \((S_m, \ldots, S_{2m})\) has two equal rows) and in the case \(i = j\), \(B_{ii} = D_{2m}\) for \(i = 1, \ldots, m\).

Note that we are using the right inner product (3.1) which gives for all \(p \times p\) matrices \(A\) and \(B\)
\[ < PA, QB > = A^T < P, Q > B. \]

Therefore, if \(L_m\) is the leading coefficient of \(P_m(t)\) we have from the previous calculations
\[ (3.3) \quad \quad < P_m, P_m > = L_m^T \text{diag}(D_{2m}, \ldots, D_{2m}) = L_m^T \Delta_{2m} \]
where the last line defines the diagonal matrix \(\Delta_{2m} \in \mathbb{R}^{p \times p}\). The leading coefficient of the polynomial \(H_{2m-1}(t)\) can be now calculated by noting that the leading coefficient \(L_m\) of \(H_{ij}\) is obtained by deleting the row and column corresponding to \(t^n\) [i.e. the \((mp + j)\)th row and \((mp + i)\)th column] and multiplying by \((-1)^{i+j}\). The same value is obviously obtained by deleting the same row and column in the matrix \(H_{2m}\) defined in (2.11) and calculating the resulting determinant, which is denoted by \(\Delta_{2m}^{pm_{i+j}, pm_{i+j}}\). Observing that the matrix
\[ ((-1)^{i+j} \Delta_{2m}^{pm_{i+j}, pm_{i+j}})_{i,j=1} \]

is proportional to the block in the position \((m + 1, m + 1)\) of the matrix \(H^{-1}_{2m}\) (by Cramer’s rule) we obtain from the definition of \(S_{2m}^{-1}\) in (2.13)
\[ L_m = ((-1)^{i+j} \Delta_{2m}^{pm_{i+j}, pm_{i+j}})_{ij=1} \]
\[ \quad = D_{2m} \left[ S_{2m} - (S_m, \ldots, S_{2m-1})H^{-1}_{2m-2} \left( \begin{array}{c} S_m \\ \vdots \\ S_{2m-1} \end{array} \right) \right]^{-1} \]
\[ \quad = D_{2m}(S_{2m} - S_{2m}^{-1})^{-1}, \]
which proves the remaining assertion of Theorem 3.1. \(\Box\)

It follows from Theorem 3.1 that the monic orthogonal polynomials are given by
where we have to multiply from the right, because we use the right inner product. The matrix orthogonal polynomials with respect to the measure \( td\mu(t) \) are obtained similarly and given in the following Theorem. The proof is left to the reader.

**Theorem 3.2:** The polynomials \( Q_m(t) \) defined by

\[
Q_m(t) = H_{2m}(t) = (K_{ij}(t))_{i,j=1}^p
\]

with

\[
K_{ij}(t) = \begin{vmatrix}
S_1 & S_2 & \cdots & S_{m+1} \\
S_2 & S_3 & \cdots & S_{m+2} \\
\vdots & \vdots & \ddots & \vdots \\
S_m & S_{m+1} & \cdots & S_{2m} \\
S_{m+1} & S_{m+2} & \cdots & S_{2m+1}
\end{vmatrix}
\]

are the right orthogonal polynomials with respect to the matrix measure \( td\mu(t) \). Moreover, the leading coefficient of \( Q_m(t) \) is given by

\[
K_m = ((-1)^i+j \frac{D_{2m+1}^{mp+i,mp+j}_{ij=1}}{D_{2m+1}^{mp+i,mp+j}})^p = \frac{D_{2m+1}^p}{D_{2m+1}^{mp+i,mp+j}} (S_{2m+1} - S_{2m+1}^*)^{-1}.
\]

where \( D_{2m+1} = |H_{2m+1}| \) and \( D_{2m+1}^{mp+i,mp+j} \) denotes the determinant of the matrix which is obtained from \( H_{2m+1} \) by deleting the \((mp+i)\)th column and \((mp+j)\)th row.

We finally note that it follows from the proof of Theorem 3.2

\[
< Q_m, Q_m >^* = K_m^T \text{diag}(D_{2m+1}, \cdots, D_{2m+1})
\]

\[
= K_m^T \Delta_{2m+1}.
\]

where, \(<,>^* \) is the right inner product with respect to the matrix measure \( td\mu(t) \), and that the monic orthogonal polynomials are given by

\[
Q_m(x) = Q_m(x)K_m^{-1} = Q_m(x) \frac{(S_{2m+1} - S_{2m+1}^*)}{D_{2m+1}}.
\]

**Lemma 3.3:**

The sequence of monic orthogonal polynomials \( \{P_k(x)\}_{k \geq 0} \) with respect to the matrix measure \( \mu \) satisfies the recurrence formula \( P_0(x) = I_p, P_{-1}(x) = 0 \) and for \( m \geq 0 \)

\[
xP_m(x) = P_{m+1}(x) + P_m(x)\left(\zeta_{2m+1} + \zeta_{2m}\right) + P_{m-1}(x)\zeta_{2m} - \zeta_{2m+1},
\]

where the quantities \( \zeta_j \in \mathbb{R}^{p \times p} \) are defined by \( \zeta_0 = 0, \zeta_1 = P_1, \zeta_j = Q_{j-1}P_j \) if \( j \geq 2 \).
Similarly, the sequence of monic orthogonal polynomials \( \{ Q_n(x) \}_{n \geq 0} \) with respect to the matrix measure \( x \, d\mu(x) \) satisfies the recurrence formula

\[ Q_0(x) = I_p, \quad Q_{-1}(x) = 0 \]  
and for \( m \geq 0 \)

\[
x Q_m(x) = Q_{m+1}(x) + Q_m(x) \left( \zeta_{2m+1} + \zeta_{2m+2} \right) + Q_{m-1}(x) \zeta_{2m} \zeta_{2m+1}.
\]

**Proof:** The recurrence formula for the orthogonal polynomials will be obtained by using the two sets of polynomials \( P_n(x) \) and \( Q_n(x) \) and the two recurrence formula

\[ P_{n+1}(x) = xQ_n(x) - P_n(x)A_m \]

and

\[ Q_{n+1}(x) = P_{n+1}(x) - Q_n(x)B_m. \]

These identities follow by multiplying the right hand sides with \( x^k \) and integrating with respect to the measures \( d\mu(x) \) and \( x \, d\mu(x) \), respectively. By an appropriate definition of the matrices \( A_m \) and \( B_m \) in the case \( k = m \) it follows that the multiplied and integrated right hand sides of (3.13) and (3.14) vanish and consequently these terms are the monic orthogonal matrix polynomials with respect to the measures \( d\mu(x) \) and \( x \, d\mu(x) \), respectively.

From (3.13) we get that

\[ 0 = < P_m, P_{m+1} > = < P_m, xQ_m > - < P_m, P_m > A_m. \]

Observing the identity (3.3) in the proof of Theorem 3.1 we obtain

\[ < P_m, P_m > = (I_m^{-1})^T < P_m, P_m > I_m^{-1} \]

\[ = (I_m^{-1})^T I_m^T \Delta_m I_m^{-1} = \Delta_m I_m^{-1} \]

\[ = S_{2m} - S_{2m}^- \]

and similarly [recall (3.8) - (3.10)]

\[ < P_m, xQ_m > = < P_m, xQ_m > K_m^{-1} = (K_m^{-1})^T < Q_m, Q_m >^* K_m^{-1} \]

\[ = \Delta_{2m+1} K_m^{-1} = S_{2m+1} - S_{2m+1}^- \]

which yields [observing the definition of \( \zeta_j \) in (2.33)]

\[ A_m = (S_{2m} - S_{2m}^-)^{-1} (S_{2m+1} - S_{2m+1}^-) = \zeta_{2m+1} \]

Similarly, we can multiply the representation (3.14) by \( Q_m \) and take the inner product with respect to the matrix measure \( t \, d\mu(t) \) to get

\[ B_m = (S_{2m+1} - S_{2m+1}^-)^{-1} (S_{2m+2} - S_{2m+2}^-) = \zeta_{2m+2} \]
To combine the two recurrence formula (3.13) and (3.14) into one recurrence formula for the sequence of monic orthogonal polynomials $P_n$ we write
\[ Q_n(x) = x^{-1}(P_{n+1}(x) + P_n(x)A_m) \]
which gives
\[ P_n(x) = Q_n(x) + Q_{n-1}(x)B_{m-1} \]
\[ = x^{-1}(P_{n+1}(x) + P_n(x)A_m) + x^{-1}(P_n(x) + P_{n-1}(x)A_{m-1})B_{m-1} \]
or equivalently
\[ (3.17) \quad xP_n(x) = P_{n+1}(x)(A_m + B_{m-1}) + P_{n-1}(x)A_{m-1}B_{m-1} \]
From (2.33), (3.15) and (3.16) we have $A_m = \zeta_{2m+1}$ and $B_{m-1} = \zeta_{2m}$ where $\zeta_k = Q_{k-1}P_k$, which proves the first assertion of the lemma. The second part follows by similar arguments and the corresponding proof is therefore omitted. \qed

4 Favard’s Theorem on the interval $[0, 1]$

Using the results of sections 2 and 3 we have the following result.

**Theorem 4.1:**

a) If $\{P_n\}_{n \geq 1}$ is the sequence of monic polynomials which are orthogonal with respect to the matrix measure $\mu$ on the interval $[0, 1]$ then the sequence satisfies the recurrence formula (3.11) where the coefficients $\zeta_n = Q_{n-1}P_n$ in the recursion satisfy (2.34) and (2.35).

b) Conversely, if the sequence of monic polynomials $\{P_n\}_{n \geq 1}$ satisfies the recurrence formula (3.11) where the $\zeta_n$ form a chain sequence (i.e. there exist matrices $P_n$ and $Q_n$ such that $\zeta_n = Q_{n-1}P_n$ and satisfy (2.34) and (2.35) with $S_0 = I$, then there exists a matrix measure $\mu$ supported on the interval $[0, 1]$ for which the polynomials $\{P_n\}_{n \geq 1}$ are the corresponding monic orthogonal matrix polynomials.

**Proof:** Part a) has already been shown above. For part b) we define the corresponding moment sequence to obtain the measure $\mu$. To do this we let $S_0 = I_P$, $S_1 = P_1$ and successively define $S_n$ for $n \geq 2$ by setting
\[ (4.1) \quad S_n = S_n^- + D_nP_n. \]
Recall that $S_n^-$ is defined in (2.13) and depends only on $S_0, S_1, \cdots, S_{n-1}$. If the matrix canonical moments $P_n$ are such that (2.34) and (2.35) hold, then it follows that
\[ (4.2) \quad S_n^- < S_n < S_n^+. \]
In this case the defined sequence is such that \((S_0, S_1, \ldots, S_n)\) is in the interior of \(M_{n+1}\) for each \(n\). Any corresponding sequence of measures will converge to a measure \(\mu\) with the moments \(S_n\) for all \(n \in \mathbb{N}\).

The sequence of monic orthogonal polynomials from this measure \(\mu\) will satisfy the same recurrence formulas so these must be the sequence \(\{P_n\}_{n \geq 1}\) because the monic orthogonal polynomials are unique. \(\square\)

**Example 4.2:** Consider the matrix measure discussed in Example 2.9. We have

\[
\zeta_{2k-1} = \frac{k}{2(2k-1)} \begin{pmatrix} 1 & \frac{1}{2k} \\ \frac{1}{2k} & 1 \end{pmatrix}, \quad \zeta_{2k} = \frac{k}{2(2k+1)} \begin{pmatrix} 1 & -\frac{1}{2k} \\ -\frac{1}{2k} & 1 \end{pmatrix},
\]

which gives for the monic orthogonal polynomials with respect to the matrix measure \(d\mu(x)\) the following recursions

\[
P_0(x) = I_2,
\]

\[
P_1(x) = xP_0(x) - \zeta_1 = \begin{pmatrix} x - \frac{1}{2} & x - \frac{1}{4} \\ x - \frac{1}{2} & x - \frac{1}{2} \end{pmatrix},
\]

\[
P_{k+1}(x) = (x - \frac{1}{2})P_k(x) - \frac{1}{16}P_{k-1}(x), \quad k \geq 1.
\]

5 Favard’s Theorem for the interval \([0, \infty)\)

Most of the material above can be extended to the interval \([0, \infty)\). All the results in Section 2 remain valid up to Theorem 2.5. If the matrix polynomial satisfies \(P(t) \geq 0\) on \([0, \infty)\) then corresponding to Theorem 2.5 we have the following representation theorem for nonnegative definite matrix polynomials.

**Theorem 5.1:** If \(P_n(t)\) is a nonnegative definite matrix polynomial of degree \(n\) for all \(t \in [0, \infty)\), then there exist matrix polynomials \(B_j(t)\) and \(C_j(t)\) of degree \(j\) such that

\[
P_{2m}(t) = B_m(t)B_m(t)^T + tC_{m-1}(t)C_{m-1}(t)^T
\]

if \(n = 2m\) is even, and

\[
P_{2m+1}(t) = tB_m(t)B_m(t)^T + C_m(t)C_m(t)^T
\]

if \(n = 2m+1\) is odd.

**Proof:** If \(P(t) \geq 0\) on \([0, \infty)\) then certainly \(P(t) \geq 0\) on \([0, b]\). We can rewrite the result from Theorem 2.5 by a change of variable to get, for the case \(n = 2m\) for example, that

\[
P_{2m}(t) = B_m(t)B_m(t)^T + \frac{t}{b}(1 - \frac{t}{b})C_{m-1}(t)C_{m-1}(t)^T
\]

20
where the polynomials $B_m$ and $C_{m-1}$ depend on $b$. We want to consider the case $b \to \infty$. To do this we note that
\[ c^T P_{2m}(t)c \geq c^T B_m(t)B_m(t)^T c \]
for all vectors $c \in \mathbb{R}^n$. Letting $c$ be the vector with a one in a single component it follows that all the coefficients of the matrix polynomial $B_m(t)$ are bounded and we can take convergent subsequences. Similarly, we obtain a subsequence for the part $b^{-1}C_{m-1}(t)C_{m-1}(t)^T$ and considering the limit for this subsequence yields the representation (5.1), which proves the assertion for $n = 2m$ even. The odd case $n = 2m + 1$ is similar and therefore omitted. \[ \square \]

**Theorem 5.2:**

a) The point $(S_0, S_1, \ldots, S_n)$ is contained in the moment space $M_{n+1}$ on the interval $[0, \infty)$ if and only if $\underline{H}_n$ is nonnegative definite.

b) The point $(S_0, S_1, \ldots, S_n)$ is contained in the interior of moment space $M_{n+1}$ on the interval $[0, \infty)$ if and only if $\underline{H}_n$ is positive definite.

If the space of consideration is the interval $[0, \infty)$ a lower bound for the moments $S_k$ is available but not an upper bound. The lower bound is precisely as before, that is
\[ S_{n+1} - S_{n+1}^- = h_n^{T} \underline{H}_{n-1}^{-1} h_n \geq 0 \]
provided that $\underline{H}_{n-1}$ is nonsingular. The quantity
\[ \zeta_k = (S_{k-1} - S_{k-1}^-)^{-1}(S_k - S_k^-) \]
is defined as in (2.33) and we can trivially write
\[ S_n - S_n^- = S_0 \zeta_1 \zeta_1 \cdots \zeta_n > 0 \]
if $(S_0, \ldots, S_n)$ is in the interior of the moment space $M_{n+1}$. The systems of polynomials $P_m(t)$ and $Q_m(t)$ are defined as before and the analysis regarding these is the same, except no mention is now made of the canonical moments $P_k$. Thus we have the following refinement of Favard's theorem on the nonnegative line $[0, \infty)$.

**Theorem 5.3:**

a) If $\left\{ P_n \right\}_{n \geq 1}$ is the sequence of monic polynomials which are orthogonal with respect to the matrix measure $\mu$ on the interval $[0, \infty)$, then the sequence satisfies the recurrence formula (3.11) where the coefficients $\zeta_n$ satisfy (5.4)

\[ \zeta_1 \zeta_1 \cdots \zeta_n > 0 \]
if $(S_0, \ldots, S_n)$ is in the interior of the moment space $M_{n+1}$. The systems of polynomials $P_m(t)$ and $Q_m(t)$ are defined as before and the analysis regarding these is the same, except no mention is now made of the canonical moments $P_k$. Thus we have the following refinement of Favard's theorem on the nonnegative line $[0, \infty)$.

b) Conversely, if the sequence of monic polynomials $\left\{ P_n \right\}_{n \geq 1}$ satisfies the recurrence formula (3.11), where the coefficients $\zeta_n$ satisfy (5.4) with $S_0 = I$, then there exists a matrix measure $\mu$ supported on the interval $[0, \infty)$ for which the polynomials $\left\{ P_n \right\}_{n \geq 1}$ are the corresponding monic orthogonal polynomials.
Proof: The proof is very similar to the proof of Theorem 4.1. Part a) is again immediate. For part b) we define the moment sequence by letting $S_0 = I$, $S_1 = \zeta_1$ and successively define

$$S_n = S_n^- + \zeta_1 \zeta_2 \cdots \zeta_n$$

The conditions in (5.4) insure that for each $n$, $S_n > S_n^-$ and the proof proceeds as in Theorem 4.1.
